NATURE

A WEEKLY JOURNAL OF SCIENCE

213
28/9/66

Volume 209

JANUARY 1, 1966, to MARCH 26, 1966

(19) March

LONDON

MACMILLAN (JOURNALS), LTD.

NEW YORK: ST. MARTIN'S PRESS, INC.

Wanting 5029.

DATES and PAGINATION of WEEKLY ISSUES

Serial No.		*Date of issue*		*Pagination*
5018	...	January	1	1–112
5019	...	,,	8	113–226
5020	...	,,	15	227–330
5021	...	,,	22	331–436
5022	...	,,	29	437–540
5023	...	February	5	541–644
5024	...	,,	12	645–742
5025	...	,,	19	743–838
5026	...	,,	26	839–944
5027	...	March	5	945–1052
5028	...	,,	12	1053–1160
5029	...	,,	19	1161–1270
5030	...	,,	26	1271–1374

INDEX

Aarons, Dr. Jules (edited by) : Solar System Radio Astronomy, *review* by J. H. Thomson, 117
Abdel Rahman, Dr S., and Decker, Prof. P. : Comparative Study of the Urease in the Rumen Wall and Rumen Content, 618
Aberdeen : University of, Appointments, 1073
Abiogenic Origin of Some Naturally Occurring Hydrocarbons : Possible (Dr. C. Ponnamperuma and K. Pering), 979–82
Abo-El-Enein, Dr. M. A., and Wyke, Dr. B. : Laryngeal Myotatic Reflexes, 682–6
Abraham, Hilda C., and Freud, E. L. (edited by) : Psycho-Analytic Dialogue : Letters of Sigmund Freud and Karl Abraham, 1907–1926, *review* by Dr. C. Allen, 1274
Abraham : Psycho-Analytic Dialogue : Letters of Sigmund Freud and Karl (edited by H. C. Abraham and E. L. Freud), *review* by Dr. C. Allen, 1274
Absorbers : Life-times of Saturable (P. W. A. Bowe et *al.*), 65
Absorption in the Earth's Atmosphere : Collision-induced (C. B. Farmer and Dr. J. T. Houghton), 1341
Absorption of Pralidoxime and other Aldoximes : Intestinal (Prof. R. R. Lovine and Dr G. M. Steinberg), 269–71
Absorption Spectra of Methylene Blue in Benzene (Prof. S. R. Palit and G. K. Saxena), 1127
Academy of Sciences of the U.S.S.R. : Foreign Members, 760
(Acanthocephala) . Uptake of Small Particles by *Moniliformis dubius* (Dr. S. J. Edmonds and B. R. Dixon), 99
(Acari : Tetranychidae) : Intersterility as a Consequence of Insecticide Selections in *Tetranychus urticae* Koch (W. P. J. Overmeer), 321
Accident . Antarctic Crevasse (Sir Vivian Fuchs and Dr. G. de Q. Robin), 18
Accident at Windscale : A Peak in the Tritium Content of Atmospheric Hydrogen following the (D. H. Ehhalt and A. E. Bainbridge), 903
Accumulation of Excessive Doses of Iodide by the Thyroid Gland of Normal, Hypophysectomized and Thyroxine-treated Rats (Dr. I. Posner and Dr. E. Pimentel), 514
Acetic Acid and its Reactions with Olefines : Formation of Mercuric Iodo-acetate in Glacial (T. D. Smith), 907
Acetylcholine : Prolonged Survival of Isolated Frog Muscle and its Sensitivity to (Dr. A. J. Harris and Prof. R. Miledi) 716
Acetylsalicylic Acid in Man : Urinary Excretion of (A.J. Cummings and M. L. King), 620
Acha, I. García, Aguirre, M. J. R., Lopez-Belmonte, F., and Villanueva, Dr. J. R. : Use of Lipase and Strepzyme for the Isolation of 'Protoplasts' from Fungal Mycelium, 95
Acidic Degradation for the Determination of the Distribution of Pyrimidine Nucleotides in Deoxyribonucleic Acids : Use of (Dr. A. S. Jones, J. R. Tittensor and Dr. R. T. Walker), 296
Ackerman, Prof. Eugene and Strickland, Prof E. H. : Highly Damped Oscillations in a Peroxidase-like Enzyme Reaction, 405
Acridoidea : African Genera of (Dr. V. M. Dirsh), Published for the Anti-Locust Research Centre, *review* by Sir Vincent Wigglesworth, 1059
Acta Physica 860
('Actamer') on *Fasciola hepatica* : Some Apparent Effects of Bithionol (Prof. B. Dawes), 424
Activation Analysis : Guide to (edited by W. S. Lyon, jun.), *review* by T. B. Pierce, 9
Activity of Small Animals using Repetitive Electronic Flash : Photographic Method of Recording the (J. Gage), 933
Actomyosin : A Factor inhibiting the Adenosine Triphosphatase Activity and the Superprecipitation of (D. J. Hartshorne *et al.*), 1352
(Acute Phase) Globulin of Rat Serum by the Liver : Synthesis of α_2—AP (D. C. Benjamin and Prof. H. E. Weimer), 1032
Adám, Gyorgy, Adey, Prof. W. R., and Porter, Prof. R. W. : Interoceptive Conditional Response in Cortical Neurones, 920
Adaptation of Bovine Sweat Glands to a Hot Environment (D. M. Murray), 431
Adaptation to Life Underground : The Mole : its (V. C. Barber), 971
Adelie Penguin : Secretion of the Thiocyanate Ion by the Nasal Gland of the (Prof D. S. Douglas), 1150
Adenine from Deoxyribonucleic Acid by Hydrogen Peroxide : Liberation of (Prof. K. Yamafuji and Dr. Y. Uchida), 301
Adenosine Deaminase . Investigation of Plant Seeds for (Prof. T. G. Brady and V. J. Hegarty), 1027
Adenosine Inhibition of Platelet Aggregation in the Presence of Cardiac Glycosides : Enhanced (F. Michal and Prof. R. H. Thorp), 208
Adenosine Triphosphatase Activity and the Superprecipitation of Actomyosin : A Factor inhibiting the (D. J. Hartshorne, Prof. S. V. Perry and V. Davies) 1352
Adenosine triphosphatase (ATPase) in Boar Epididymal Spermatozoon : Presence of Sodium-Potassium-stimulated (S. Uesugi and S. Yamazoe), 403
Adenosinetriphosphatase (ATPase) Inhibitor in the Rat : Experimentally produced Cerebral Status Spongiosus and Continuous Pseudorhythmic Electroencephalographic Discharges with a Membrane- (A. Bignami and G. Palladini), 413
Adenosinetriphosphatase (ATPase) in Normal and Leukaemic Granulocytes : Histochemical Demonstration of Sodium-Potassium-activated (Dr. S. Szmigielski), 412
Adenosine Triphosphate by Human Erythrocyte Ghosts : Formation of (G. Ronquist and Prof. G. Ågren), 1090
Adenovirus, Isolation of a Poxvirus from Stock Type 12 (D. L. Huxsoll and Dr. M. Pollard), 1157
Adenovirus 12 Oncogenicity in Hamsters by Simultaneous Inoculation with Adenovirus 5 Inhibition of (J. Peries, J. C. Chuat, M. Canivet and Prof. M. Boiron), 738
Adenylate Kinase in Man : Genetically Determined Variation of (Dr. R. A. Fildes and Prof. H. Harris), 261–3
Adey, Prof. W. Ross, *et al.* : Interoceptive Conditional Response in Cortical Neurones, 920
Stereotaxic Atlas of the Chimpanzee Brain (*Pan satyrus*), *review* by Prof. R. L. Holmes, 950
Adgie, R. L., and Gent, H. : Positions of Radio Sources determined by the Interferometer at the Royal Radar Establishment, 549–51
Adhesion and Adhesives (edited by Dr. R. Houwink and Dr. G. Salomon) Vol. I, Second Revised Edition, *review* by Dr. R. P. Sheldon, 7
Adhesion of Lymphocytes to Large Motile Cells in Cultures of Rabbit Thymus (Dr. J. A. Sharp), 628
Adhesiveness of Red Cells : Effect of Basic Proteins on the (Dr. E. Ponder), 307
Adhesives : Adhesion and (edited by Dr. R. Houwink and Dr. G. Salomon), Vol. I, Second Revised Edition, *review* by Dr. R. P. Sheldon, 7
Adin, A., and Sykes, Dr. A. G. : Electron-transfer Reactions of Europium (II) in Aqueous Perchloric Acid Solutions, 804
Adipose Tissue : Fatty Acid Composition of Triglycerides from ([The late] Dr. M. J. R. Hawkins and J. F. Stevens), 1145
Adjuvants : Stimulation of Phagocytosis in Relation to the Mechanism of Action of (Prof. T. Nicol *et al.*), 1142
Adler, Prof. Saul : *Obituary* by Prof. P. C. C. Garnham, 1286
Administering Research and Development (C. D. Orth, Prof. J. C. Bailey and F. W. Wolek), *review* by W. Jackson, 1061
Adrenal Corticoidogenesis : Effect of Oestradiol in (Prof. J. I. Kitay), 808
Adrenal Medulla : Various Cell Types in the (I. Benedeczky, A. Puppi, A. Tigyi and Prof. K. Lissák), 592–4
Adrenal Necrosis caused by Dimethylbenzanthracene : Role of Lysosomes in (Dr. A. C. Allison and J. T. Dingle), 303
Adrenaline- and Noradrenaline-storing Cells in the Electron Microscope : Mechanism of a Histochemical Reaction differentiating between (Prof. R. E. Coupland and Dr D. Hopwood), 590
Advisory Council on Technology : New Members, 860
Aedes aegypti Mosquitoes : Resistance to a Chemosterilant, Metepa, in (W. Klassen and Prof. F. Matsumura), 1155
Aeration on the Consumption of Ethanol by the Isolated Perfused Rat Liver : Effect of (E. R. Gordon), 1028
Aerodynamics : Elements of Hypersonic (Dr. R. N. Cox and Dr. L. F. Crabtree), *review* by Prof. A. D. Young, 1163
Aeronautics, Cranfield : Appointment of Professor and Head of the Department of Mathematics at the College of, 454
Aerosol Deposition in the Lungs of Space Travellers (Dr. D. C. Muir), 921
Aflatoxin : Carcinoma of the Glandular Stomach in Rats given Diets containing (Dr. W. H. Butler and Dr. J. M. Barnes), 90
Experimental Detoxification of Groundnut Meals containing (T. J. Coomes *et al.*), 406
A Site of Action in the Rat Liver Cell (J. I. Clifford and Dr. K. R. Rees), 312
Aflatoxin in Sheep : Excretion of the 'Milk Toxin' : Metabolism of (Dr. R. Allcroft *et al.*), 154
Africa : Man and (edited by Dr. G. Wolstenholme and M. O'Connor), *review* by Dr. A. S. Thomas, 548
African Genera of Acridoidea (Dr. V. M. Dirsh), *review* by Sir Vincent Wigglesworth, 1059
African Husbandman (W. Allan), *review* by Miss H. L. Hutchinson, 8
Agarics : New Method for Isolating Tetrads of (D. Moore), 1157
Age of the Anorthosites in the Norwegian Caledonian Chain (I. Hernes), 191
Age, Cardiac Output and Choice Reaction Time (J. Szafran), 836
Age of the Faeroes : New Data on the Geological (J. Rasmussen and Prof. A. Noe-Nygaard), 1229
Age : Motor Unit in Old (E. Gutmann and V. Hanzlíková), 921
Age on Serum-bound Sialic Acid in Rats : Effect of (D. H. Dall and J. E. Richmond), 303
Ages of Minerals from the Pre-Cambrian Complex of the Malverns : Isotopic (Dr. R. St. J. Lambert and D. C. Rex), 605
Ages of Some Volcanic Rocks from the Galapagos Islands : Palaeomagnetism and Potassium-Argon (Dr. A. Cox and Dr. G. B. Dalrymple), 776
Agents capable of morphologically transforming Hamster Cells *in vitro* : Isolation of Unidentified (Dr. A. D. Vizoso, R. Hay and T. Battersby), 1263
Aggregation of Malignant and Non-Malignant Mammalian Cells : Differences in Patterns of (Prof. B. Halpern *et al.*), 157–9
Aggregation in the Presence of Cardiac Glycosides : Enhanced Adenosine Inhibition of Platelet (F. Michal and Prof. R. H. Thorp), 208
Aggregation of Tumour Cells (Prof. E. O. Dodson), 40–4
Aggregations of Entities of Varied Size and Shapes as seen in Mosaics : Pattern Formation in (Richard E. M. Moore), 128
Agostoni, Dr. Angelo, Vergani, C., and Villa, L. : Intracellular Distribution of the Different Forms of Lactic Dehydrogenase, 1024
Ågren, Prof. Gunnar and Ronquist, G. : Formation of Adenosine Triphosphate by Human Erythrocyte Ghosts, 1090
Agricultural Research Council 1963–65 : Report of the (Prof. A. N. Duckham), 358
Agricultural Studentships : Postgraduate, 138
Agriculture : Ministry of, Headship of Plant Pathology Division, 134
Agrobacterium tumefaciens induced by Ultra-violet Light Radiation, Fixed *L*-forms of (Dr M. Rubio-Huertos and E. Cabezas de Herrera), 1262
Aguirre, M. J. R., *et al.* Use of Lipase and Strepzyme for the Isolation of 'Protoplasts' from Fungal Mycelium, 95
Ahmad, P. M., *et al.* : Metabolism of Dimethyl Sulphoxide to Dimethyl Sulphone in the Rat and Man, 619
Ahrenfeldt, R. H., *et al.* : Mental Health in a Changing World, *review* by Dr. C. Allen, 119
Aid to Developing Countries, 1071
Aid to India, 1288
Aid Overseas : British Government, 965, 966

Aid in its Proper Perspective : Overseas, 437
Air Bubbles : Ion Separation in Bursting (Dr. M. R. Bloch et *al*), 802
Airborne Observations of Natural Radioactivity (Prof F Běhounek), 1342
Air-burst Debris : Radionuclide Fractionation in (Dr. E. C. Freiling and M A. Kay), 236–8
Air : Clean, 27
Hydrogen Content of the (R. J. W Kershaw), 190
Air Turbulence : Atmospheric Clear (Dr. R. L. Moore and Prof T. N. Krishnamurti), 462–4
Air by a Water Jet Surface Entrainment of (A. T. Sheridan), 799
Aircraft Industry . Future of the British, 1053–7
Akhiezer, A. I., and Berestetskii, V. B Quantum Electrodynamics, Second Edition, *review* by Prof. P. M. Davidson, 121
Akinesia : Investigations on 3, 4-Dimethoxyphenylethylamine : Pharmacology of (Prof A. Barbeau et *al.*), 719–21
Akkad, I El, and Hobson, Dr. P. N : Effect of Antibiotics on Some Rumen and Intestinal Bacteria, 1046
Aladjem, Prof. Frederick : Immunoelectrophoretic Properties of Low-density Human Serum Lipoproteins, 1003–5
Alaskan Earthquake of March 1964, 857
Albert, Dr S , Wolf, P., Pryjma, I , and Moore, W : Differentiation of Nucleated Red Blood Cells during *in vivo* Culture of Mouse Spleen and Thymus Cell Suspensions, 320
Albin, Dr. Maurice S , et *al* . Prolonged Whole-brainRefrigeration with Electrical and Metabolic Recovery, 1320–2
Alcock, Prof. C. B. : Free Energy Functions and Deviations in Thermochemical Data Storage for Inorganic Compounds, 198
Alcohol Consumption, Effects of, on the Activity of Liver Enzymes in *C57BL/Crgl* Mice (Dr K Schlesinger, Dr E. L Bennett, M Hebert and Prof. G. E. McClearn, 488
Alcohol to Ethyl Esters of Fatty Acids by the Lactating Goat : Conversion of (Prof S Patton and Dr R. D McCarthy), 616
Alcohol-soluble Fractions of Pea Seedlings . Effect of Plant Regulators on the Incorporation of Phosphorus-32 into the (Dr E Koves and Dr. F. Sirokmán), 420
Alcohol-Water Mixtures : Anomalies in Contact Angle Behaviour for Ethyl (A B Ponter et *al.*), 540
Aldermaston . Mass Spectrometry Data Centre for, 455
Aldoximes : Intestinal Absorption of Pralidoxime and other (Prof R. R. Levine and Dr G. M Steinberg), 269–71
Alexander, Dr. D. Pauline, et *al.* Influence of Umbilical Blood Fructose on the Production of Fructose by the Perfused Placenta of the Sheep, 918
Alexander, Dr. P., Hieger, Dr. I., and Levene, Dr. A. L. : Progress of Cancer Research, 554–8
Alexander, Dr. P : Radiotherapeutics and Radiobiology, *review*, 557
Alexander, Dr. R. McN. : The Mammals a Guide to the Living Species, *review*, 443
Alexander, W. B. : *Obituary* by Dr. D. Lack, 759
Alexandrov, Dr. V. A.: Analysis of the Lethal Effect of 'Myleran' on Rat Embryos, 1215
Alga *Anabaena cylindrica* Metabolic Activities of Isolated Heterocysts of the Blue-green (Dr. P. Fay and A. E. Walsby), 94
Alga *Prototheca zopfii* : Adaptive Butyrase Enzyme System in the (Dr. D. R. Cullimore), 531
Algae : Structure and Reproduction of the (F. E. Fritsch), Two Volumes, *review* by Prof. G E. Fogg, 1277
Algal Development in Yellowstone and Iceland Hot Springs : Temperature Optima for (Prof. T. D. Brock and Mrs. M. L. Brock), 733
Algal Influence on Radionuclides in Settling Ponds (J. Echo and D. B. Hawk i , 1105–7
Alkali Metal Ions of the Racemization of the *Tris*-oxalato Chromium-III Anion : Catalysis by (J. A. Kernohan et *al.*), 906
Alkaline Phosphatase : Action of Neuraminidase on Human Kidney (P. J. Butterworth and Dr. D. W. Moss), 805
Alkaline Phosphatase Activities : Separation of Serum 5′-Nucleotidase and Non-Specific (Dr. D. W. Moss), 806
Alkaline Phosphatase Activity in the Pancreatic Islets of Rats : Effect of Glucagon on the (Inge-Bert Taljedal et *al.*), 409
Alkaline Phosphatase and the Philadelphia Chromosome : Regulation of Leucocyte (Prof. R. L Teplitz), 821
Alkaloids in Submerged Culture by a Strain of *Claviceps purpurea* (Fr.) Tul : Production of Peptide (Dr. A. Tonolo), 1134
Alkaloids on Thin-layer Chromatograms : Detection of Cholinesterase-inhibiting Insecticide Chemicals and Pharmaceutical (Dr. J. J. Menn and J. B. McBain), 1351
Alkyl-5-bromouracil Herbicides on a Bacteriophage : Absence of Mutagenic Effects of 3- and 6- (Dr. J. W McGahen and Dr. C. E. Hoffmann), 1241
Alkyl Iodides : Primary Process in the Photolysis of (R. J. Donovan and Dr. D. Husain), 609
Alkyl-β-D-xylopyranosides in the Presence of Mercuric Salts : Synthesis of (Dr. C K De Bruyne and Dr. F. G. Loontiens), 396
Allan, William . The African Husbandman, *review* by Miss H. L Hutchinson, 8
Allanson, Prof. B. R , Hill, B. J., Boltt, R. E., and Schultz, V. : An Estuarine Fauna in a Freshwater Lake in South Africa, 532
Allcroft, Dr. R., Rogers, H., Lewis, G., Nabney, Dr. J., and Best, P. E. : Metabolism of Aflatoxin in Sheep : Excretion of the 'Milk Toxin', 154
Alleles : Evolution of Over-dominance during the Initial Spread of New (J. K. Jain), 429
Allen, Dr. C. . Mental Health in a Changing World, *review*, 119
Psycho-Analytic Dialogue : Letters of Sigmund Freud and Karl Abraham, 1907–1926, *review*, 1274
Allen, Deena, and Maxwell, Dr. R. E. : Interactions of ε-Aminocaproic Acid with the Thrombin Clotting and Fibrinolytic Systems, 211
Allen, Prof. Frank : *Obituary* by Prof. J. F. Allen, 133
Allen, Prof. James C. : Gm(b) Factor in the γ globulin of Non-human Primates, 520
Allen, Prof. J. F : *Obituray* of Prof. Frank Allen, 133
Allen, Dr. Joan M., and Reif, Prof A. E. : Mouse Thymic Iso-antigens, 521
Mouse Nervous Tissue Iso-antigens, 523
Allen, Ronald V., et *al.* : Evaporation of Lava and its Condensation from the Vapour Phase in Terrestrial and Lunar Volcanism, 445–8
Aller, H. D., Jensen, C. J., and Malville, J. M. : Pre-absorption Events at 230 Mc/s, 1014
Allergic Encephalomyelitis : Glucose Metabolism of Central Nervous Tissues in Rats with Experimental (Dr. M. Edmonds Smith), 1031
Allewijn, F. T. N., et *al* : Tetramisole (R 8299), a New, Potent Broad Spectrum Anthelmintic, 1084–6
Alley, C O , et *al.* : Backscattering from the Upper Atmosphere (75–160 Km) detected by Optical Radar, 798
Allibone, Dr. T. E. : Future of Nuclear Power, 766
Proceedings of the Third International Conference on the Peaceful Uses of Atomic Energy, 1964, Vol. I, *review*, 1272
Allison, Dr. A. C. : Le Message Héréditaire, *review*, 750
Allison, Dr. A. C., and Dingle, J. T. : Role of Lysosomes in Adrenal Necrosis caused by Dimethylbenzanthracene, 303
Allison, Dr. A. C., Magnus, Dr. I A., and Young, M. R. : Role of Lysosomes and of Cell Membranes in Photosensitization, 874–8
Allison, Prof S K. : *Obituary* by Prof H. L Anderson, 758
Allium cepa . Effect of Malachite Green, Congo Red and Safranin on Cell Division in Gemmae of (L. Rejniak and H. Piotrowska), 517
Allometric Growth of Ammonoid Shells : A Generalization of the Logarithm Spiral (Dr. T B Burnaby), 904–6
Alloys : Theory of Transformations in Metals and (Dr. J. W Christian), *review* by Prof. C R. Tottle, 648
Allsopp, Dr. A. : Plant Anatomy, Second Edition, *review*, 443
Al-Nagdy, Sohair, Miller, D. S , Qureshi, Dr. R. U., and Yudkin, Prof. J. : Metabolic Differences between Starch and Sucrose, 81
Alnus Pollen Grain : Degradation of Arci in a Fossil (W. C. Elsik), 825
Alpers, Dr. M., et *al* : Experimental Transmission of a Kuru-like Syndrome to Chimpanzees, 794–6
Alpert, Paul F , and Hays, Dr. E. F. : Infectivity of Gross and Rauscher Leukaemia Viruses and their Nucleic Acids, 1326
α-Chains of Tropocollagen : 3, 2, 1 : A, B, C Sub-unit Hypothesis for the (Prof. P. M. Gallop), 73
α-Hydroxybutyric Dehydrogenase Activity of Human Vascular Tissue (R. Sanwald and Prof. J. E. Kirk), 912
α-Keratin : Structure of (H. J. Woods and C. N Tyson), 399
Alphonsus Structure of the Crater (L. B. Ronca), 182
Alternating Current Resistivity Profiles through Anodic Oxide Films on Aluminium and its Alloys (Dr. G. C. Wood and Dr. A. J Brock), 773–5
Alternating Electric Field : Coacervate Behaviour in an (Prof A. E. Smith and M A. C. Chance), 74
Altschuler, N , et *al* Influence of Cold on Thyroid Uptake of Iodine-131 and Circulating Iodine Compounds, 1240
Altstein, Dr. A. D., Dodonova, N N., and Vassiljeva, N. N. . Small-plaque and Large-plaque Variants of Papova Virus SV_{40}, 1048
Aluminium and its Alloys A.C. Resistivity Profiles through Anodic Oxide Films on (Dr G. C. Wood and Dr A. J. Brock), 773–5
Aluminium-Copper-Magnesium Alloy : *T*-phase Precipitation induced by the Addition of Silver to an (J. H. Auld et *al.*), 703
Ambrosius, Prof H : Comparative Investigation of Immune Globulins of Various Vertebrate Classes, 524
Ambystoma gracile: Temperature-controlled Meristic Variation in the Salamander (Prof. C. C. Lindsey), 1152
America : Science in Nineteenth-Century (edited by N. Reingold) *review* by Dr. E. H Hutten, 235
American Association for the Advancement of Science : President-elect, 1288
American Indians : Xg Blood Groups of (W. Bouman et *al.*), 411
American Museum of Natural History, 1178
Amines in Central Nervous Tissue : Electron Microscopic Localization of (Prof J. G. Wood), 1131
Amines : Liquid Ion-exchange Extraction of some Physiologically Active (Dr. D M. Temple and R. Gillespie), 714
Amino-acid and Incorporation in Isolated Rabbit Diaphragm : Effect of Vitamin E Deficiency on Uptake of (Prof J F. Diehl), 75
Amino-acid Pool in Avian Tissues . Nature of the Free (Prof R. L. Squibb), 710
Amino-acid Sequence near the Disulphide Bridges of Bence-Jones Proteins : Variations in (Dr. C. Milstein), 370–3
Amino-acids in the Bleeding Sap of Wheat, Maize and Rice : Comparison of the Spectrum of (G Palfi), 636
Amino-acids and Mandelic Acid with Isotopic Hydrogen : Stereospecific Catalytic Labelling of (G E. Calf et *al.*), 502
Amino-acids : Stereochemical Relationship between Coding Triplets and (Dr. S. R. Pelc and Miss M. G. E. Welton), 868–70
Specificity of the Stereochemical Relationship between Ribonucleic Acid-triplets and (Miss M. G E. Welton and Dr. S. R. Pelc), 870–2
para-Aminobenzoic Acid : Antagonism of Calistin-sulphonamide Synergism by (Dr G R. Gale and C A. Odell), 1357
γ-Aminobutyric Acid : Inhibition of *Ascaris* Muscle by (Dr. A. S. F. Ash and J. F Tucker), 306
ε-Amino-caproic Acid with the Thrombin Clotting and Fibrinolytic Systems : Interactions of (Dr. R. E. Maxwell and D. Allen), 211
Amino-groups and C-Terminal of Sperm-Whale Myoglobin in the Antigen-Antibody Reaction : Role of the (Prof. M. Z. Atassi), 1209–11
Amir, Dr. S. M., Barker, Dr. S. A., Butt, Dr. W. R., and Crooke, Dr. A. C. : Purification and Lability of Human Follicle-stimulating Hormone, 1092
Ammah-Attoh, V. : Development of *Boophilus decoloratus* on the Ox, 629
Ammonium Salts on Concrete : Action of, 665
Ammonium Thiophosphite, Isolation of, by means of Preparative Ion-exchange Chromatography (Dr. F. H. Pollard, Dr. G Nickless and J. D. Murray), 396
Ammonoid Shells : Allometric Growth of (Dr. T. P. Burnaby), 904–6
Amoroso, Prof. E C., et *al* : Fructose as a Component of the Foetal Blood and Foetal Fluids of the Bush Baby (*Galago senegalensis senegalensis*), 300
Amyloidosis in Mice with a Transplantable Plasma Cell Tumour (Dr. T. Lehner, Dr. V. M. Rosenoer and N. E. Topping), 930
Anabaena cylindrica : Metabolic Activities of Isolated Heterocysts of the Blue-green Alga (Dr. P. Fay and A. E. Walsby), 94
Analysis : Guide to Activation (edited by W. S. Lyon, jun), *review* by T. B. Pierce, 9
Analysis of Polycrystalline Materials : Handbook of X-ray (Dr. L. I. Mirkin), *review* by Dr. E. G. Steward, 6
Anaphylaxis : Release of Ganglioside from Guinea-pig Lung Tissue during (Dr. W. G Smith), 1251
Anbar, Prof. M., Meyerstein, D., and Neta, P. : Reactivity of Aromatic Compounds towards Hydrogen Atoms, 1348
Andersen, A. J C , and Williams, P. N. : Margarine : Second Revised Edition, *review* by H. Lavery, 1060
Anderson, A. D. : Existence of a Significant Latitudinal Variation in Density from 200 to 800 Kilometres, 656–61
Anderson, Dr. A. R., Knight, B., and Winter, J. A. : Effect of Temperature on the γ-Radiolysis of Water Vapour, 199
Anderson, Dr. E. S. : Possible Importance of Transfer Factors in Bacterial Evolution, 637
Anderson, Prof. H. L. : *Obituary* of Prof. S. K. Allison, 758
Anderson, Prof. N. H. : Depressant Effect of Moonlight on Activity of Aquatic Insects, 319
Anderson, Wirtley A., et *al.* : Leptomeningeal Sarcomata and Gliomata induced in Rabbits by Rous Sarcoma Virus, 524
Anderson, W. R., et *al.* : Induction of Multiple Brain Tumours (Gliomata and Leptomeningeal Sarcomata) in Dogs by Rous Sarcoma Virus, 884–6
Andrade, Prof. E. N da C. : Scientific Papers by Lord Rayleigh, Six Volumes, 1869–1919, *review*, 4
Andrews, Dr. P. : Molecular Weights of Prolactins and Pituitary Growth Hormones estimated by Gel Filtration, 155–7

Anemone : Continuous Recording of the Hydrostatic Pressure in a Sea (E. R. Trueman), 830
Angiotensin on Plasma Free Fatty Acid and Blood Glucose-levels : Effects of Synthetic (Prof. J. Nakano and T. Kusakari), 922
Angles of Liquids on Organic Solids : Contact (Dr. G R. Lester), 1126
Anglo-French Co-operation in Oceanography, 1288
Angular Diameters of Some Radio Sources with Anomalous High-Frequency Spectra, (D. Barber, W. Donaldson, G. K. Miley and H. Smith), 753–5
Anharmonic Oscillations in Electrical Potential at Probe Electrodes in Membrane Transport Cells (Prof J. W. Lorimer and T. C. Brydges), 1019; (Chaim Forgacs), 1019
Animals in Captivity (P Street), *review* by George Cansdale, 1277
Anisotropic Big-bang Cosmology · Helium Production in an (Dr. S W. Hawking and Dr R. J. Tayler), 1278
Anlagen of *Ephestia kuhniella* Z *in vitro* : Effect of Zinc Ions on Mitosis in Wing (Dr C. A. Barlow), 1045
Anodic Oxide Films on Aluminium and its Alloys : A.C. Resistivity Profiles through (Dr. G. C. Wood and Dr A. J Brock), 773–5
Anodic Photocurrent and the Primary Process in Electrochemical Photoeffect (Dr M. Heyrovský), 708
Anamalous Dispersion of the Faraday Effect in Haemoglobin and Myoglobin (Prof M. V Volkenstein *et al*), 709
Anomalous High-frequency Spectra Angular Diameters of Some Radio Sources with (D. Barber *et al.*), 753–5
Anorthosites in the Norwegian Caledonian Chain Age of the (I. Hernes), 191
Antarctic Crevasse Accident : J. T. Bailey, D. P Wild, and Dr. J. K. Wilson (Sir Vivian Fuchs and Dr G. de.Q. Robin), 18
Antarctica Wind Drainage off the High Plateau of Eastern (K. B. Mather and G. S. Miller), 281–4
Anthelmintic : Tetramisole (*R* 8299), a New, Potent Broad Spectrum (D. Thienpont *et al*), 1084–6
Anther and Pollen Development in a Stamen-less Tomato Mutant. Gibberellin-induced (Dr. S C. Phatak *et al.*), 635
Anthocerosis : Sporogenesis in the Bryophyte (J. E. Ridgway and Prof D. A Larson), 1154
(Anthomyiidae) on Sorghum due to Spraying · Increases in the Incidence of *Atherigona indica infuscata* Emden Diptera (J C Davies and D. Jowett), 104
Anthropology · Its Achievements and Future (Prof C Levi-Strauss), 10–13
Antibiotic Resistance in *Staphylococcus aureus* Specificity and Prevention of (S J. De Courcy, jun , and Prof. M. G. Sevag), 373–6
Antibiotics on Some Rumen and Intestinal Bacteria : Effect of (I. El Akkad and Dr P. N Hobson), 1046
Antibodies in Experimental Infections of *Schistosoma mansoni* and the Passive Transfer of Resistance : Reagin-like (Dr B M Ogilvie *et al*), 1221–3
Antibodies in the Fluid of the Conjunctival Sac of Trachoma Patients : Fluorescent (Prof H. Bernkopf *et al*), 725
Antibody Capacity Immuno-adsorbents of High (J. C. Metcalfe *et al*), 1142
Antibody Method, Failure of the, to demonstrate a Circulating Hormonal Factor after Partial Hepatectomy (Dr. T. A. Hyde, Dr L. J. Hipkin and Dr J. C. Davis), 1034
Antibody Production in the *Cyclo*-phosphamide- or Methotrexate-treated Rat : 19S and 7S (Prof G. W Santos and Dr A H Owens, jun.), 622
Anticholinesterase Compounds in Live Rats : Liver Metabolism of (T. B Gaines *et al*), 88
Anticoagulant Fraction of Incubated Fibrinogen : Variable and Invariable Components of the (Prof E. Triantaphyllopoulos and Prof. D. C. Triantaphyllopoulos), 265–7
Anti-fouling Compositions (Dr. P. de Wolf and Dr A. M. van Londen), 272–4
Antigen-Antibody Reaction Role of the Amino groups and C-Terminal of Sperm-whale Myoglobin in the (Prof. M. Z. Atassi), 1209–11
Antigen cross-reacting with Human Blood Group A Substance : Presence in Colic Glandular Cells of Various Mammalian Species of an (A. Zweibaum *et al.*), 159–61
Antigen of *Escherichia coli* · K88, an Episome-determined Protein (Dr. S Stirm *et al.*), 507
Antigen-induced Morphological Changes in Germ-free Mice (P. Caster, R. Garner, and Prof T. D. Luckey), 1202–4
Antigenic Characteristics of DNA Protein from a Canine Haemangiopericytoma (Prof. R H Wilson *et al*), 1102–5
Antigenic Stimulation of Rabbits · Autoradiographic Investigation of Tissues after Primary and Multiple (Dr. J. S Garvey and Prof D H Campbell), 1201
Antigenicity of a Carboxymethylcellulose Bovine Serum Albumin Glycoprotein in Conventional and Germ-free Mice (Prof D. Platt, J E Bicanovsky, M H Dalbow and Prof J C Thonard), 214
Antigens : Chemical Deletion of Histocompatability (E Bonmassar *et al*), 1141
Antihaemophilic Globulin a Protein? : Is the (H. A Veder), 202
Anti-matter and Optical Asymmetry : Quasars, (Dr. T L. V. Ulbricht), 391
Antimicrobial Agents and Chemotherapy, 358
Antimicrobial Drugs : Synergism of Three (Dr. D. Kaplan and Dr. W. Koch), 718
Antiphlogistic Activity and under Clinical Treatment . Serum Concentration of Phenylbutazone in Tests for (E. Kampmann and Prof. H.-H. Frey), 519
Antiquity of the Ubeidiya Hominid : Relative (T. I. Molleson and Dr. K P. Oakley), 1268
Anti-serum in India : Supply of, 966
Anti-tumour Activity of Immune Lymphoid Cells · Inhibitory Effect of Carcinostatic Agents on (Dr Y. Hashimoto *et al.*), 1360
Anti-tumour Agent . Chemical Nature of Free Retine, an (Dr. C. Marmasse), 1346
Antiviral Agents . Possible Correlation between Virus Particle Size and Activity of (Dr D. J. Bauer), 639
Antral Mucosa : Isolation of Two Gastrins from Human (Prof. R A. Gregory *et al.*), 583
Anya, A O. : Localization of Ribonucleic Acid in the Cuticle of Nematodes, 827
Aoki, Dr Susan, Boyce, Prof R. P., and Howard-Flanders, Prof P. : Sensitization of *Escherichia coli* to Radiation by Bromouracil . Excessive Post-irradiation Breakdown of Deoxyribonucleic Acid without Concomitant Synthesis, 686–8
Aortic Beta-glucuronidase Activity with Progressively Severe Arteriosclerosis in Female Breeder Rats : Increased (Prof. B. C. Wexler and Dr. J. T. Judd), 383–6
Aortic Polysaccharide-Protein Complexes · Solubility in Phenol of (Dr. J R. Dunstone and M. D Franek), 508
Apffel, Dr C A., Arnason, Dr. B. G , and Peters, Dr. J. H. Induction of Tumour Immunity with Tumour Cells treated with Iodoacetate, 694–6
Apneustic Breathing, and the Neural Control of Respiration : Cerebellar Activity, (Prof. R L Glasser *et al.*), 810–12
Apoproteins of some Haemoglobins and Myoglobins : Infra-red Spectral Analysis of the (Prof M Z. Atassi and L R Cacciotti), 1211–3
Apparatus for Dynamic Thin-layer Chromatography (H. L. Kay), 1237
Appelman, A. W. M., *et al.* · Interphase Death and Related Biochemical Radiation Effects in Murine Leukaemia Cells, 1149
Applecross Group : Palaeogeography of the Torridonian (G. E. Williams), 1303–6
April : Night Sky in, 1074
Aquatic Insects : Depressant Effect of Moonlight on Activity of. (Prof. N. H. Anderson), 319
Aranda, L. C., and Luco, Dr J. V. : Reversibility of an Electrical Correlate to the Process of Learning, 205
Arch Dams : Theory of (edited by J. R. Rydzewski), Symposium 1964, *review* by Dr. A C. Cassel , 949
Archeology : Introduction to Pleistocene Geography : Environment and (K. W. Butzer), *review* by B. W Sparks, 845
Archibald, Dr. A R , *et al.*: Changes in Wall Teichoic Acid resulting from Mutations of *Staphylococcus* aureus, 484–6
Arcs in a Fossil *Alnus* Pollen Grain : Degradation of (W. C. Elsik), 825
Arctic Stratigraphy, 967
Ardao, Dr. M I., Sosa Perdomo, C., and Pellaton, M. G. : Venom of the *Megalopyge urens* (Berg) Caterpillar, 1139
Argentine . Hypocuprosis of Cattle in the (J B. Bingley and B. J. Carrillo), 834
Argon Analyses Simplified Bulb Tracer System for (M A. Lanphere and Dr. G. B. Dalrymple), 902
Argon : Ionization Relaxation in Slightly Impure (Dr. N. R. Jones and Dr M. McChesney), 1080
Argon and Krypton . Thermodynamics of Liquid Mixtures of (A G. Duncan *et al.*), 1236
Argon and Oxygen using Molecular Sieve : Chromatographic Separation of (J. A. J. Walker), 197
Argon Retentivity of Nepheline (R. M. Macintyre, Prof. D York and Prof. J. Gittins), 702
Arid Soil Crusts : Nitrogen Fixation by Lichens of (R. W. Rogers *et al*), 96
Armitage, Dr. A. 300 Jahre Physik und Astronomie an der Kieler Universität, *review*, 745
Armitage, Prof. P · Computers in Biomedical Research : Vol. I, *review*, 233
Armstrong, Dr. J. A . Intracellular Membraneous Structure, *review*, 336
Arnason, Dr Barry G., *et al.* : Induction of Tumour Immunity with Tumour Cells treated with Iodoacetate, 694–6
Aromatic Compounds in Acidic, Neutral and Alkaline Aqueous Solutions : Radiation-induced Nitration of (R. K Broszkiewicz), 1235
Aromatic Compounds to Bovine Serum Albumin . Binding of (Dr. M. R. V. Sahyun), 613
Aromatic Compounds towards Hydrogen Atoms . Reactivity of (Prof. M. Anbar, D Meyerstein and E. Neta), 1348
Arsenic Pressure on Dislocation Densities in Melt-grown Gallium Arsenide : Effect of (J. C. Brice and G. D. King), 1346
Arteriosclerosis in Female Breeder Rats Increased Aortic Beta-glucuronidase Activity with Progressively severe (Prof. B. C. Wexler and Dr. J T. Judd), 383–6
Arthrobotrys oligospora Fresenius : Carbon- and Nitrogen-levels of a Medium in Relation to Growth and Nematophagous Activity of (Th H. A Olthof and Prof. R. H Estey), 1158
Arthur, Prof Robert M. : Comparison of Oxygen Demand Rates and Oxygen Utilization Rates, 104
Articulated Ship, 965
Arylhydroxamic Acid with High Carcinogenic Activity *N*-Hydroxy-2-fluorenylbenzamide, an (Prof. H R. Gutmann *et al.*), 202
Asbestos Company Ltd Cape, 858
Ascaris Muscle, Inhibition of, by γ-Aminobutyric Acid : a Possible New Assay Method (Dr A. S F. Ash and J. F. Tucker), 306
Ascaris suum : P_2 Blood Group Substance in *Lumbricus terrestris* (Earthworm) and (Prof O. Prokop and D Schlesinger), 1255
Ascites Tumour Production · Rapid (Dr D N. Wheatley), 1255
Ascorbic Acid in the Larval Stages of *Plusia signata* (Lepidoptera · Noctuidae) (Dr. P. N Saxena), 535
Ash, Dr. A. S F , and Tucker, J. F : Inhibition of *Ascaris* Muscle by γ-Aminobutyric Acid : a Possible New Assay Method, 306
Asheshov, E. H., and Winkler, Prof K. C *Staphylococcus aureus* Strains in the '52, 52A, 80, 81 Complex', 638
Aspartic Acids in Whole Rumen Contents : Metabolism of Glutamic and (A V. Portugal and Dr T. M. Sutherland), 510
Aspergillus nidulans : Somatically Unstable Mutants of (A. Upshall), 1113–5
Assessment Procedures in Secondary School Science (R. Weatherall), 357
Asthma and Testosterone (Dr. E. R Trethewie), 1136
Aston in Birmingham : University of, Professor of Civil Engineering, 454
Astronomie an der Kieler Universität 300 Jahre Physik und (C. Schmidt-Schonbeck), *review* by Dr. A. Armitage, 745
Astronomy · Solar System Radio (edited by Dr J Aarons), NATO Lectures, Athens, 1964, *review* by J H. Thomson, 117
Astrophysics and a Possible Sub-nuclear Energy Source : High-energy (Dr. F. Pacini), 389
Asymmetry Quasars, Anti-matter and Optical (Dr. T. L. V. Ulbricht), 391
Atassi, Prof M Z. : Role of the Amino Groups and C-Terminal of Sperm-whale Myoglobin in the Antigen-Antibody Reaction, 1209–11
Atassi, Prof. M. Z., and Cacciotti, L. R. : Infra-red Spectral Analysis of the Apoproteins of Some Haemoglobins and Myoglobins, 1211–3
Atherigona indica infuscata Emden Diptera (Anthomyiidae) on Sorghum due to Spraying · Increases in the Incidence of (J C. Davies and D Jowett), 104
Atherosclerosis : Comparative (edited by J. C. Roberts, R. Straus and M S. Cooper), *review* by H. Selye, 847
Atherton, Dr N. M., and Morton, J. R. : Electron Spin Resonance Spectrum of $NH_3^+SO_2^-$, 294
Atlas of Steroid Spectra W. Neudert and H. Ropke), *review* by Prof. W. B. Whalley, 5
Atmosphere · Collision-induced Absorption in the Earth's (C. B Farmer and Dr. J. T Houghton), 1341
Atmosphere Laser Probing the Lower (B. R. Clemesha *et al.*), 184
Atmosphere (75-160 Km) detected by Optical Radar : Backscattering from the Upper (P D. McCormick *et al*), 798
Atmospheric Carbon-14 Content during the Past Three Millennia in Relation to Temperature and Solar Activity (Dr. J. R. Bray), 1065–7
Atmospheric Clear Air Turbulence (Dr. R L. Moore and Prof. T. N. Krishnamurti), 462–4
Atmospheric Hydrogen following the Accident at Windscale : A Peak in the Tritium Content of (D. H. Ehhalt and A. E. Bainbridge), 903
Atmospheric Nitrogen-15 to Higher Plants, Availability of Biologically Fixed (Dr. H. F. Mayland and Prof. T. H. McIntosh), 421
Atmospheric Precipitations : An Explanation for the Irregular Ion Ratios in (Dr. M R. Bloch *et al*), 802
Atmospheric Shock Waves · Reflectivity of (W R Mallory), 175–7
Atmospheric and Space Electricity : Problems of (edited by S C. Coroniti) *review* by Sir Basil Schonland, 440
Atomic Energy Authority : Eleventh Annual Report, 1965 : United Kingdom, 354
Non-nuclear Research : U.K , 663
Prototype Fast Reactor : U.K., 856
Atomic Energy, 1964 . Vol. I · Proceedings of the Third International Conference on the Peaceful Uses of, *review* by Dr. T. E. Allibone, 1272
Atomic Energy Research Establishment, Harwell . Deputy Director, 1176

Atomic Mass per Nucleon as a Parameter for Nuclides rather than the Conventional Packing Fraction : Superiority of (H. B. Klepp), 1344
Atomic Spectroscopy : Coincidence Tables for (J. Kuba *et al.*), *review* by L. Bovey, 847
Atoms on a Lattice-vacancy Diffusional Process : Effect of Interstitial (G. A. Davies *et al.*), 1125
Attenuation of Shock Waves by Cooling (J. C. Muirhead), 64
Attractants in some Australian Scorpion Flies : Specificity of Male Sex (Dr. G. F. Bornemissza), 732
Auckland Institute and Museum, 561
Audus, Prof. L. J., *et al.* : Root Cap and the Perception of Gravity, 93
Auerbach, Susan, and Gwatkin, R. B. L. : Synthesis of a Ribonucleic Acid Virus by the Mammalian Ovum, 993
Auersperg, Dr. Nelly : Differential Heat Sensitivity of Cells in Tissue Culture, 415
Auld, J. H., Vletz, J. T., and Polmear, I. J. : T-phase Precipitation Induced by the Addition of Silver to an Aluminium-Copper-Magnesium Alloy, 703
Aurbach, Dr. G. D., *et al* : Evaluation by Radioimmunoassay of Factors controlling the Secretion of Parathyroid Hormone, 52–7
Perfusion of the Isolated Parathyroid Gland of the Goat and Sheep, 55
Aureomycin and the Cultured Pearl Industry, 22
Auroral Effects and Excess Energy Electrons (E H. Hirsch), 390
Aurothioglucose Sensitivity of *CBA* Mice injected at Two Different Times of Day (Dr. P. R. Wiepkema), 937
Australia : Baas Becking Biogeological Research Laboratory, Canberra, (J. E. Falk), 669
Origin of Silcretes of Central (Prof. W. D. Bruckner; Dr. C. G. Stephens), 496
Phyllocarid Crustacean Fauna of European Aspect from the Devonian of Western (Dr. W. D. I. Rolfe), 192
Soils on Quaternary Beach Ridges in South, 21
Australia and New Zealand : Life Insurance Medical Research Fund of, 967
Australian Museum · South, 561
Australian Scorpion Flies : Specificity of Male Sex Attractants in some (Dr. G. F. Bornemissza), 732
Australopithecines : *Homo habilis*, *Homo erectus* and the (Dr. L. S. B. Leakey), 1279–81
Autolysis in *Bacillus cereus* T. : Stabilization of (Dr. M. Goldman), 321
Autolysis by Hyperbaric Oxygen : Regulation of Cellular (Dr R. M. Rosenbaum *et al.*), 895
Autoplastic Chimerae of the Domestic Fowl : Inter-breed, Intra-breed and (P. N. Martinovitch *et al.*), 816
Autoradiographic Evidence suggesting *in vivo* Transformation of Some Blood Mononuclears in Repair and Fibrosis (Dr. T. Gillman and L. J. Wright), 1086–90
Autoradiographic Investigation : DNA Synthesis of Hydatidiform Moles in Organ Culture : an (Prof. H. Márquez-Moncer), 1037
Autoradiographic Investigation of Tissues after Primary and Multiple Antigenic Stimulation of Rabbits (Dr. J. S. Garvey and Prof. D. H. Campbell), 1201
Autoradiography as a Tool in Microbial Ecology (Prof. T. D Brock and Mrs. M. L Brock), 734–6
Auxospore Formation in the Marine Centric Diatom *Coscinodiscus concinnus* W. Smith : Short-term Temperature and Light Conditions associated with (Dr. R. W. Holmes), 217
Availability of Biologically Fixed Atmospheric Nitrogen-15 to Higher Plants (Dr. H. F. Mayland and Prof. T. H. McIntosh), 421

Campylonotidae : Protandrous Hermaphroditism in Decapod Prawns of the Families Hippolytidae and (J. C. Yaldwyn), 1366
Canada : National Research Council of, 351
National Museum of, Anthropology Papers, 351
University Research in, 562
Canadian Universities : Geography in (Prof. W. G. V. Balchin and A. M. Coleman), 960–3
Canary Islands · Volcanic Chronology of Lanzarote, (K J. Tinkler), 1122
Canberra, Australia : Baas Becking Biogeological Research Laboratory, (J. E. Falk), 669
Cancer · Carcinogenesis and the Biology of, *review* by Dr. I Hieger, 554–7
Chromosomes and (H. Van Steenis), 819
Clinicopathology of, *review* by Dr A. L Levene, 558
European Journal of (D. A. Brunning), 668
Nature of (P. M. Sutton) *review* by R J. C. Harris, 1167
Symptoms as an Index of Biological Behaviour and Prognosis in Human (Prof. A R. Feinstein), 241–5
Cancer Cells : Lack of Communication between (Prof. W R. Loewenstein and Dr. Y. Kanno), 1248
Cancer Research : Fundamental (Dr S. Itzhaki), 257
Cancer Research : Progress of (Dr. P. Alexander, Dr. I Hieger and Dr. A L. Levene), *review* of Forty-second Annual Report of the British Empire Cancer Campaign for Research for 1964, 554–8
Cane, Dr. R. F. · Microwave Stimulation of Chemical Reactions, 197
Canine and Feline Nutritional Requirements (edited by O. Graham-Jones), Symposium, 1964, *review* by P. R. Payne, 847
Canivet, M., et *al* : Inhibition of Adenovirus 12 Oncogenicity in Hamsters by Simultaneous Inoculation with Adenovirus 5, 738
Cano-Ruiz, J , et *al.* : Measurement of Graphitic Acid Surface with Polar Molecules, 906
Cansdale, George : Animals in Captivity, *review*, 1277
Capacity and Sales Balancing, 248
Cape Asbestos Company Ltd., 858
Captivity : Animals in (P. Street), *review* by G. Cansdale, 1277
Carbide Phase in the Liquid State : Graphite-Carbide Materials prepared by Hot-working with the (Dr. J. L. White and J. M Pontelandolfo), 1018
Carbon-14 Content during the Past Three Millennia in Relation to Temperature and Solar Activity : Atmospheric (Dr. J R. Bray), 1065–7
Carbon- and Nitrogen-levels of a Medium in Relation to Growth and Nematophagous Activity of *Arthrobotrys oligospora* Fresenius (Th. H. A. Olthof and Prof. R. H. Estey), 1158
Carbon and to Palaeosalinity in certain British Upper Carboniferous Sediments Boron Content in Relation to Organic (Dr. R. M. C. Eagar and Dr. D. A. Spears), 177–81
Carbon Dioxide Assimilation by Glasshouse Crops : Measurement and Control of the Rate of (Dr. J. V Lake), 97
Carbon Dioxide on the Shattering of Freezing Water Drops · Effect of (J. E. Dye and Prof. P V. Hobbs), 464–6
Carbon Dioxide through Thin Layers of Solution : Diffusion of (I S. Longmuir et *al.*), 393
Carbon Tetrachloride in the Rat : a Speculative Mechanism based on Activation Necrogenic Action of (Dr. T. F Slater), 36–40
Carbonic Anhydrase in the Uterus of Hens during Moult : Behaviour of (J. Schluns and T. Diamantstein), 304
Carboxymethylcellulose Bovine Serum Albumin Glycoprotein in Conventional and Germ-free Mice Antigenicity of a (Prof. D. Platt et *al.*), 214
Carcinogenesis and the Biology of Cancer, *review* by Dr. I Hieger, 554–7
Carcinogenesis : Genome Mutation and (J W I M. Simons), 818
Carcinogenic Action : Instability of some of the Products formed by the Action of *N*-Methyl-*N*-nitrosourethane on Cysteine *in vitro* Role of Neighbouring Groups in Enzymatic and (Dr. R. Schoental), 148–51
Carcinogenic Activity · *N*-Hydroxy-2-fluorenylbenzamide, an Arylhydroxamic Acid with High (Prof. H. R Gutmann et *al.*), 202
Carcinogenic Activity of *N*-Methyl-*N*-nitroso-*N'*-nitroguanidine (Dr. R. Schoental), 726
Carcinogenic Activity *in situ* of Further Steroid Compounds (Prof. A. Lacassagne, Prof. N. P. Buu-Hoï and Prof. F. Zajdela), 1026
Carcinoma of the Glandular Stomach in Rats given Diets containing Aflatoxin (Dr. W. H. Butler and Dr. J. M. Barnes), 90

Carcinoma in the Rat : Evidence for the Cell-free Transmission of Chemically-induced Mammary (Dr. J. Scholler *et al.*), 1037
Carcinostatic Agents on Anti-tumour Activity of Immune Lymphoid Cells : Inhibitory Effect of (Dr. Y. Hashimoto, H. Sudo and Prof. M. Ishidate), 1360
Cardiac Glycosides : Enhanced Adenosine Inhibition of Platelet Aggregation in the Presence of (F. Michal and Prof. R H. Thorp), 208
Cardiac Muscle : Variable Diastolic Ventricular Compliance : a General Property of Mammalian (Dr. B. J. Scherlag *et al*), 1246–8
Cardiac Output and Choice Reaction Time : Age, (J. Szafran), 836
Cardiac and Skeletal Muscle of Cats Late in Haemorrhagic Shock . Water and Electrolyte Changes in (Prof. E. D. Brand), 814
Cardin, Laurent, *et al.* : Pharmacology of Akinesia : Investigations on 3, 4-Dimethoxyphenylethylamine, 719–21
Care, Dr. Anthony D , *et al.* · Evaluation by Radioimmunoassay of Factors controlling the Secretion of Parathyroid Hormone, 52–7
Care, Dr. Anthony D., Sherwood, Dr L. M , Potts, jun , Dr J. T., and Aurbach, Dr. G. D. : Perfusion of the Isolated Parathyroid Gland of the Goat and Sheep, 55
Cargo . Road Belong (P Lawrence), *review* by Dr. P. Brown, 120
Caries and Enamel Structure Dental (Prof. H. S. M. Crabb) and K. V. Mortimer, 611
Caries-prevention : Nutrition and (edited by G. Blix), *review* by Prof. R. B. Lucas, 1275
Caries-resistant Teeth (edited by G E. W. Wolstenholme and Maeve O'Connor), Symposium, *review* by Prof. R. B. Lucas, 1275
Caries : Vanadium and Dental (Prof. D. M. Hadjimarkos), 1137
Carlisle, Dr. H J · Behavioural Significance of Hypothalamic Temperature-sensitive Cells, 1324
Carnegie, Dr. P. R., and Lumsden, Prof. C. E. Encephalitogenic Peptides from Spinal Cord, 1354

Chemistry · Vol 4, : Progress in Medicinal (edited by G. P. Ellis and G. B. West), *review* by T. S. Work, 1061
Chemistry Research · Plight of Basic, *review* of Westheimer Report, 541–3
Chemistry in the Soviet Union (Prof. J Turkevich), *review* by Dr. W. Gerrard, 334
Chemistry, Vol. 4 : Technique of Inorganic (edited by Prof. H. B. Jonassen and A. Weissberger), *review* by K. W. Bagnall, 121
Chemists : Earnings of, 460
Chemosterilant, Metepa, in *Aedes aegypti* Mosquitoes : Resistance to a (W. Klassen and Prof. F. Matsumura), 1155
Chemotherapy : Antimicrobial Agents and, 358
Chen, L. T , and Ruth, Prof. R. F. : Nuclear Structure in Lymphoid Primordia, 381–3
Chen, Dr. Raymond F. : Fluorescence Quantum Yield of 1-Dimethylamino-napthalene-5-sulphonate, 69
Chenaille, Ph., *et al.* : Investigation of Rauscher Virus Ribonucleic Acid, 680–2
Chick Embryo : Effect of Deoxyguanosine on Skeletal Development in the (Prof. L. J. Pierro and J. Spiggle), 782–5
Chicken submitted to a Poultry Diagnostic Laboratory-Esh Sarcoma Virus · Isolation of a Tumour Virus from a (Prof. A M. Wallbank *et al.*), 1265
Child Psychiatry : Modern Perspectives in (edited by Dr. J. G. Howells), *review* by Prof. O. L Zangwill, 120
Chimerae of the Domestic Fowl : Inter-breed, Intra-breed and Autoplastic (P. N. Martinovich *et al*), 816

Chimpanzee Brain : Stereotaxic Atlas of the (M. R. DeLucchi *et al.*), *review* by Prof. R. L. Holmes, 950
Chimpanzees : Experimental Transmission of a Kuru-like Syndrome to (Dr. D. C. Gajdusek *et al.*), 794–6
Chinese Nuclear Explosion in May 1965 : Fractionation Phenomena in Debris from the (G Persson), 1193–5
Chinese Nuclear Test : Observations on Debris from the First (G. Persson), 1228
Chipperfield, Dr. Barbara Ubiquinone Concentrations in Some Tumour-bearing Tissues, 1207–9
Chloramphenicol : Suppression of Schistosomiasis in Snails by (Dr. K. S. Warren and Prof. A. S Weisberger), 422
Chloride across the Cornea · Active Transport of (Prof. J. A. Zadunaisky), 1136
Chloride in Rat Liver · High Nucleo-cytoplasmic Concentration Gradient of (H. Langendorf *et al.*), 1130
Chlorophyll Content of *Deschampsia flexuosa* Seedlings grown on a Calcareous and a Non-calcareous Soil (J. A. Lee and Dr. H. W. Woolhouse), 1044
Chlorophylls in Chloroplast Fragments : Distribution of (Dr. J. A. Gross A. M. Shefner and Dr. M. J. Becker), 615
Chloroplast Fragments : Distribution of Chlorophylls in (Dr. J. A. Gross *et al.*), 615
Chlorothiazide, Effect of, on Water Consumption in the Rat (Dr. J. Gutman and M. Chaimovitz), 410
Chlorpromazine and Different Xanthene Dyes . Evidence of Complex Formation between (E. Lábos), 201
Choice Reaction Time Age, Cardiac Output and (J Szafran), 836
Choline Acetyltransferase, Inhibition of, by Excess Cysteine (Dr. D. Morris, Dr C. Hebb and G. Bull), 914
Cholinesterase in the Mammalian Kidney (J. Fourman), 812
Cholinesterase-inhibiting Insecticide Chemicals and Pharmaceutical Alkaloids on Thin-layer Chromatograms : Detection of (Dr. J. J. Menn and J. B. McBain), 1351
Choong Shin-Piaw, Prof., Wang Loong-Sen, and Lim Yoke-Seng : Emission Band Systems of Ag_2 produced in Discharge, 1300–2
Chorio-allantoic Membrane Lesions produced by Inoculation of Adult Fowl Small Lymphocytes (Dr. M. J. Simons and Dr. R. Fowler), 588–9
Christian, Dr. J. W. : Theory of Transformations in Metals and Alloys, *review* by Prof. C. R. Tottle, 648
Christiansen, Prof W. N , and Wellington, K. J. : A New Radiotelescope of 40 sec-of-arc Resolving Power for Southern Sky Observations, 1173–6
Christophorou, Dr. L. G., and Carter, J. G. : Excimer X-ray Investigation, 678–80
Chromatids in Diplochromosomes of Endo-reduplicated Cells after Uptake of Tritiated Thymidine : Position of Labelled (Dr. H. G. Schwarzacher and W. Schnedl), 107
Chromatograms · Detection of Cholinesterase-Inhibiting Insecticide Chemicals and Pharmaceutical Alkaloids on Thin-layer (Dr. J. J. Menn and J. B. McBain), 1351
Chromatographic Injection Study of some of the Parameters involved in Split-stream (Dr. M. J. E. Golay), 502
Chromatographic Separation of Argon and Oxygen using Molecular Sieve (J. A. J. Walker), 197
Chromatography : Apparatus for Dynamic Thin-layer (H. L. Kay), 1237
Identification of Eluted Components in Gas (C. G. Scott), 1296
Isolation of Ammonium Thiophosphite by means of Preparative Ion-exchange ([The late] Dr. F. H Pollard *et al.*), 396
Separation of Oxygen Isotopes by Gas (W. Bocola *et al.*), 200
Tritium Enrichment by Gas (Dr. H. Perschke), 1021
Chromium and Rhodium : Radio-Chemistry of, 967
Chromophoric Reagents for Labelling the Thiol Groups of Proteins : New, 457
Chromosomal Constitution of Human Endometrium (Dr. E. C. Hughes and Dr. T. V. Csermely), 326
Chromosome Abnormalities in Lymphatic Leukaemia in Cattle (Prof. W. C. D. Hare and R. A. McFeely), 108
Chromosome Abnormalities in Two State Hospitals for Patients requiring Special Security Sex (Dr. M. D. Casey *et al.*), 641
Chromosome Alterations in Monkey Kidney Cells infected *in vitro* with Herpes Simplex Virus Early Diffuse (Prof. M. Boiron, Dr. J. Tanzer, M. Thomas and A Hampe), 737
Chromosome Duplication : Synchrony of (Dr. C. W. Gilbert *et al*), 537
Chromosome Exchanges and the Spatial Arrangement of Chromosome Strands in Interphase Nucleus . Kinetics of Two-break (Dr. Sushil Kumar and Dr. A. T Natarajan), 796
Chromosome Injuries in Mouse Bone Marrow under the Distant Effect of Ionizing Radiation · Induction of (N. F. Barakina and M. I. Yanushevskaya), 823
Chromosome : Regulation of Leucocyte Alkaline Phosphatase and the Philadelphia (Prof. R. L. Teplitz), 821
Chromosomes and Cancer (H. van Steenis), 819
Chromosomes : Electron Micrography of Human (Dr. A. Govaerts and D. Dekegel), 831
Evidence for a 'Folded-fibre' Organization in Human (Prof. E. J. DuPraw), 577–81
Chuat, J. C., *et al.* : Inhibition of Adenovirus 12 Oncogenicity in Hamsters by Simultaneous Inoculation with Adenovirus 5, 738
Chubb, Dr. James C. : Key to Parasites of Freshwater Fish of the U.S.S R., *review*, 749
Cifelli, Dr. Richard, Bowen, Dr. Vaughan T., and Siever, Prof. R. : Cemented Foraminiferal Oozes from the Mid-Atlantic Ridge, 32–4
Cigarette Smokers : Polonium-210 Activity in the Lungs of (Prof. B. Rajewsky and Dr. W. Stahlhofen), 1312
Cinemicrography in Cell Biology (edited by Dr. G. G. Rose), *review* by E. Lucey, 651
Circadian Rhythms in the Feeding Behaviour of *CBA* Mice (Dr. P. R. Wiepkema, L. de Ruiter and J. Reddingius), 935
Circulating Hormonal Factor after Partial Hepatectomy : Failure of the Antibody Method to demonstrate a (Dr. T. A. Hyde *et al*), 1034
Circulation : Lung (Prof. D. M. Aviado), Two Volumes, *review* by Dr. C. Hebb, 230
Citellus citellus and *Spalax leucodon* : Proteolytic Enzymes of (M. I. Jankovič *et al.*), 316
Civil Service : Committee on the, 966
Organization of the Scientific, 968
Clan-system and Feeding Habits of Spotted Hyenas (*Crocuta crocuta* Erxleben) (Dr. H. Kruuk), 1257
Clark, A. G., Hitchcock, M., and Smith, Prof. J. N : Metabolism of Gammexane in Flies, Ticks and Locusts, 103

Clausen, Dr. J. Johanna, and Kozlowski, Prof. T. T. : Anatomical Responses of Pine Needles to Herbicides, 486
Claviceps purpurea (Fr.) Tul : Production of Peptide Alkaloids in Submerged Culture by a Strain of (Dr. A. Tonolo), 1134
Clay Building Bricks : Selection of, 970
Clean Air, 27
Cleavage : Site of Action of Ribonuclease during its Inhibition of Egg (Dr. D. H. Cormack), 1364
Cleaver, Dr. J. E. : Inhibition of DNA Synthesis by Ultra-violet Light under Controlled Temperature, 1317–20
Clegg, Dr. P. Catherine : Antagonism by Prostaglandins of the Responses of Various Smooth Muscle Preparations to Sympathomimetics, 1137–9
Clemesha, B. R., Kent, Dr. G. S., and Wright, Prof. R. W. H. : Laser Probing the Lower Atmosphere, 184
Clemow, Mr. John : Appointment as Head of Nuclear Physics Division, Science Research Council, 1070
Clifford, Janet I., and Rees, Dr. K. R. : Aflatoxin : a Site of Action in the Rat Liver Cell, 312
Climate : BC. 1200–A.D. 1860 : Carbon-14 and (Dr. J. R. Bray), 1065
Climate during the Last Wurm Glaciation · North Mediterranean (E. Bonatti), 984
Cline, J. F., and Wilson, D. O : Removal of Plutonium-239, Tungsten-185 and Lead-210 from Soils, 941
Cline, Dr. T. L., and Brunstein, Dr. K. A. : Possible Spectral Neutrality of Cosmic Radiation, 1186–8
Clinicopathology of Cancer, *review* by Dr A. L. Levene, 558
Clothing Insulation and Accidental Hypothermia in Youth (L. G. C Pugh), 1281–6
Clotting : Cell Dispersing Liver Extract influencing Blood (K. E. Fichtelius and B. Kullgren, 167–9
Clotting and Fibrinolytic Systems : Interactions of ε-Aminocaproic Acid with the Thrombin (Dr. R. E. Maxwell and D. Allen), 211
Cloud Structure and Distributions over the Tropical Pacific Ocean (J. S Malkus and H. Riehl), *review* by P. Graystone, 234
Clunie, Dr. J. S., *et al.* : Topotactic Dehydration of Brucite, 1083
Clunie, Dr J S , Goodman, Dr. J. F., and Ogden, C P. : Extinction Coefficient of Water at 2.93μ and Water Content of Black Foam Films, 1192
Coacervate Behaviour in an Alternating Electric Field (Prof. A. E. Smith and M. A. C Chance), 74
Coal Petrology, 21
Cockroft, Sir John, (edited by) : Organization of Research Establishments, *review* by Dr. C. P. Haskins, 946–8
Coconut Planting Material : Introduction and Exchange of (R. A. Whitehead and B. E. Thompson), 63
Coding Triplets and Amino-acids : Stereochemical Relationship between (Dr S. R. Pelc and Miss M. G. E. Welton), 868–70
Coefficient : Partition Isotherms and the Mixed Second Virial (Dr. G. F. Freeguard), 1124
(Coenzyme Q) and the Respiratory Chain : Ubiquinone (Prof. E. R. Redfearn and Dr. J. Burgos), 711–3
Coetzee, Prof. J. N , and Prozesky, Dr. O. W. : Linked Transduction in *Proteus mirabilis*, 1262
Cohen, Dr. Sidney : Drugs of Hallucination · Uses and Misuses of LSD, *review* by Dr. C. R. B. Joyce, 41
Coincidence Tables for Atomic Spectroscopy (J. Kuba, L. Kučera, F. Pizák, M. Dvorák and J. Mráz), review by L Bovey, 847
Cold on Thyroid Uptake of Iodine-131 and Circulating Iodine Compounds : Influence of (Dr. P Salvaneschi, N. Altschuler and C. Enriori), 1240
Cole, Prof. E. R., and Ujhazy, J. : Oxidation of *Cyclo*hexane by Lead Tetra-acetate, 395
Coleman, Alice M., and Balchin, Prof. W. G V. : Geography in Canadian Universities, 960–3
Colic Glandular Cells of Various Mammalian Species of an Antigen Cross-reacting with Human Blood Group A Substance : Presence in (A. Zweibaum, P. Oudea, Prof. B. Halpern and C. Veyre), 159–61
Colistin-sulphonamide Synergism by *para*-Aminobenzoic Acid : Antagonism of (Dr G. R. Gale and C. A. Odell), 1357
Collagen, Elastic Tissue and Resorcin Fuchsin (A. V. Newton), 1146
Collagen Synthesis in Fibroblasts transformed by Oncogenic Viruses (Prof. H. Green, Dr. G. J. Todaro and Prof. B. Goldberg), 916
Collagenase Activity of Immature *Fasciola hepatica* (Dr. R. M. Howell), 713
Collagenolytic Activity in Gingivae of Man (Dr H. M. Fullmer and Dr. W. Gibson), 728
Collagens and their Derived Gelatins : Partial Specific Volumes of Solubilized (Dr. P. W. Heaps *et al.*) 397
College of Aeronautics, Cranfield : Professor of Mathematics, 454
Collins, Dr. Robert L., Ordy, Dr J. M , and Samorajski, Dr. T. : Psilocin : Effects on Behaviour and Brain Serotonin in Mice, 785–7
Collision-induced Absorption in the Earth's Atmosphere (C B. Farmer and Dr. J. T. Houghton), 1341
Colony : Establishment of an Experimental Cat Breeding (Dr. H. Reinert and G. K. A. Smith), 1005–8
Colostrum Gamma-globulin : Electrophoretic Behaviour of *H* and *L* Chains of Human Serum and (Prof. J Rejnek *et al.*), 926
Colour, Magnetic Resonance and Symmetry of the Cupric Site in Blue Protein (H. J. Maria), 1023
Colour Stimulation with N-Dimethyl-amino-succinamic Acid : Inhibition of Fruit Drop and (Prof. L. J. Edgerton and Prof. M. B. Hoffman), 314
Combes, Prof. Burton, and Screnker, S . Ethionine-induced Hypoglycaemia, 911
Commonwealth Universities, 23
Communication : Is the Literature Meant for Reading? 1161
Communication, 1178
U.S. Committee on, 1161, 1176
Communication and the Control of Tissue Growth · Lack of Communication between Cancer Cells : Intercellular (Prof. W. R. Loewenstein and Dr. Y. Kanno), 1248
Complement (edited by G. E W. Wolstenholme and J. Knight), *review* by A. E. Wilkinson, 338
Complement Fixation and pH Dr. R. M. Weintraub and C Crisler), 1035
Compliance : Variable Diastolic Ventricular (Dr. B. J. Scherlag *et al.*), 1246–8
Components in Gas Chromatography : Identification of Eluted (C. G. Scott), 1296
Components of the Spore Wall of *Pithomyces chartarum* (R. J. Sturgeon), 204
Computer Applications to Process Control : Digital (edited by W. E. Miller), *review* by Dr. H. H. Rosenbrock, 948
Computer : Morphological Analysis by Digital, 858
Computer Programme Library, 965
Computers in Biomedical Research : Vol. I (edited by R. W. Stacey and B. D. Waxman), *review* by Prof. P. Armitage, 233
Computers for Research, 455
Computing Centre : National 20
Concentration of Single Stationary Drops : New Method for Determining Surface Densities by Evaluation of the Decrease in ([The late] F. H. Garner and Dr. F. J. Garfias), 1120
Concord Project, 857
Concrete : Action of Ammonium Salts on, 665
Effect of Duration of Curing on Slag-Portland Cement, 562
Conditional Response in Cortical Neurones . Interoceptive (G. Adám *et al.*), 920
Conditioned Responses from Trained Rats to Untrained Rats by means of a Brain Extract : Transfer of (Dr. F. Rosenblatt *et al.*), 46–8

Confusion Theory Explanation Muller-Lyer Haptic Illusion and a (A Watson and C. French), 942
Congo Red and Safranin on Cell Division in Gemmae of *Allium cepa* : Effect of Malachite Green, (L. Rejniak and H. Piotrowska), 517
Conjugation Process : Metabolism of *Spirogyra* during the (K Sasaki et *al*), 1042
Conjunctival Sac of Trachoma Patients : Fluorescent Antibodies in the Fluid of the (Prof. H. Bernkopf et *al.*), 725
Connolly, K. J. : Locomotor Activity in *Drosophila* as a Function of Food Deprivation, 224
Conscious Experience · The Brain and the Unity of (Sir John Eccles), *review* by Prof. W H Thorpe, 1274
Conservation : Readings in Resource Management and (edited by I. Burton et *al*), *review* by Dr. W J Eggeling, 439
Contact Angle Behaviour for Ethyl Alcohol-Water Mixtures : Anomalies in (A B. Ponter, G. A. Davies and P. G. Thornley), 504
Contact Angles of Liquids on Organic Solids (Dr. G R. Lester), 1126
Contact Angles of Mercury on Low-energy Solids (Dr V. R. Gray), 608
Contamination in Terrestrial Environments : Biological Indicator of Manganese-54 (R. Cavalloro and O. Ravera), 1259
Continents · Permanency of the (J B Carr), 341–8
Control : Digital Computer Applications to Process (edited by W. E. Miller), *review* by Dr. H. H. Rosenbrock, 948
Control of Tissue Growth : Intercellular Communication and the (Prof. W. R. Loewenstein and Dr. Y Kanno), 1248
Cooling : Attenuation of Shock Waves by (J. C. Muirhead), 64
Coombs, Prof. D. S , and Landis, C. A. : Pumice from the South Sandwich Eruption of March 1962 reaches New Zealand, 289

Dense Stars : X-ray Emission from Very (Dr. M. Surdin), 62
Densities by Evaluation of the Decrease in Concentration of Single Stationary Drops : New Method for determining Surface ([The late] F H Garner and Dr. F J Garfias), 1120
Density and Composition : Estimation of Moisture Content by Neutron Scattering : Effect of Sample (E H Waters and G F Moss), 287
Density and Direction of Molecular Flow in High Vacuum using an Ionization Gauge : Measuring the (L. Holland and C. Priesland), 274–6
Density from 200–800 Kilometres : Existence of a Significant Latitudinal Variation in (A. D Anderson), 655–61
Dental Caries and Enamel Structure (Prof H. S. M Crabb and K. V. Mortimer), 611
Dental Caries : Vanadium and (Prof. D. M. Hadjimarkos), 1137
Dentis Origin and Nature of the Cuticula (Prof. J. J. Hodson), 990–3
Deol, Dr. M. S. : Influence of the Neural Tube on the Differentiation of the Inner Ear in the Mammalian Embryo, 219
Deoxyguanosine on Skeletal Development in the Chick Embryo : Effect of (Prof. L. J. Pierro and J. Spiegle), 782–5
Deoxymyoglobin : Structure of : a Crystallographic Study (Dr. C. L. Nobbs, Dr. H. C. Watson and Dr J. C. Kendrew), 339–41
Deoxyphenylalanine in the Hydrolysate of Melanosomes from Harding-Passey Mouse Melanoma : Large Amounts of (Dr H. Takahashi and Prof. T. B. Fitzpatrick), 888–90
Deoxyribonuclease Substrate Film Methods : Ribonuclease and (Dr. B. D. Lake), 521
Deoxyribonucleic Acid Effects of the Diethyl Ester of Pyrocarbonic Acid on Bacteriophage and Transforming (I. Fedorcsák and I Turtóczky), 830
Formation of Inter-strand Cross-links in DNA and their Disappearance during Post-treatment Incubation : Effect of Carzinophillin on Bacterial (A Terawaki and Dr. J. Greenberg), 481–4
Deoxyribonucleic Acid in *Bacillus subtilis* . Transformation by Hybrid (R. Vestri, L. Felicetti and O. Lostia), 1154
Deoxyribonucleic Acid Breakdown in Bromouracil containing *Escherichia coli* exposed to Ultra-violet Light . Production of Additional Sites of (Prof. R P. Boyce), 688–91
Deoxyribonucleic Acid during the Cell Cycle of *Tetrahymena pyriformis* : Periodicity of Tritiated-thymidine Incorporation into Cytoplasmic (Dr. I. L. Cameron), 630
Deoxyribonucleic Acid without Concomitant Synthesis . Excessive Post-Irradiation Breakdown of (Dr. S Aoki *et al.*), 686–8
Deoxyribonucleic Acid by Hydrogen Peroxide . Liberation of Adenine from (Prof K Yamafuji and Dr. Y. Uchida), 301
Deoxyribonucleic Acid in *Micrococcus radiodurans* : Repair of X-ray Damage to the (Dr. C. J Dean *et al.*), 49–52
Deoxyribonucleic Acid *in vivo* when coupled to Polycation : Increased Localization and Incorporation of Iododeoxyuridine into Tumour (Dr. R. J. Woodman), 1362
Deoxyribonucleic Acid Protein from a Canine Haemangiopericytoma Antigenic Characteristics of (Prof. R. H. Wilson *et al*), 1102–5
Deoxyribonucleic Acid Synthesis of Hydatidiform Moles in Organ Culture: an Autoradiographic Investigation (Prof. H Márquez-Monter), 1037
Deoxyribonucleic Acid Synthesis by Ultra-violet Light under Controlled Temperature : Inhibition of (Dr. J. E. Cleaver), 1317–20
Deoxyribonucleic Acid Synthetic System of Bacteria damaged by Ultra-violet Light : Formation of RNA during the Recovery of the (Prof. C. O. Doudney), 528
Deoxyribonucleic Acid Template : Kinetics of Ribonucleic Acid Synthesis on (Prof. E. Ruckenstein and Dr. Z Simon), 909

Deoxyribonucleic Acids . Use of Acidic Degradation for the Determination of the Distribution of Pyrimidine Nucleotides in (Dr. A. S. Jones *et al.*), 296
Deployment of Manpower in Science and Technology, 113
Depositional Environment of British Liassic Ironstones considered in the Context of their Facies Relationships (Dr. A. Hallam), 1306–9
Depressant Effect of Moonlight on Activity of Aquatic Insects (Prof. N. H. Anderson), 319
Depression and Running in Neonatally Thymectomized Mice : Sex Difference for Immune (Dr. H. Balner and H. Dersjant), 815
Deprivation : Locomotor Activity in *Drosophila* as a Function of Food (K J Connolly,) 224
Depsides in Sunflower Leaves (Dr. A. Zane and Prof. S. H. Wender), 80
Derrick Jones, Dr. W. J , and Dover, W D. : Enhanced Diffusion Rates during the Fatigue of Metals, 704

Enriori, C., *et al* Influence of Cold on Thyroid Uptake of Iodine-131 and Circulating Iodine Compounds, 1240
Entities of Varied Size and Shapes as seen in Mosaics Pattern Formation in Aggregations of (R E. M Moore), 128
Entrainment of Air by a Water Jet Surface (A. T. Sheridan), 799
Entrainment Model for Timed Enzyme Syntheses in Bacteria (Dr. B. C. Goodwin), 479–81
Entropy and Gravitation (Prof. I Prigogine), 602
Environment . Adaptation of Bovine Sweat Glands to a Hot (D M. Murray), 431
Environment and Archeology An Introduction to Pleistocene Geography, (K. W. Butzer), *review* by B. W. Sparks, 845
Environmental Temperature and the Death Rate of Women from Neoplasms of the Breast · Relationship between (Dr. A. J Lea), 57
Enzymatic and Carcinogenic Action · Instability of some of the Products formed by the Action of *N*-Methyl-*N*-Nitrosourethane on Cysteine *in vitro*. Role of Neighbouring Groups in (Dr. R. Schoental), 148
Enzymatic Dedifferentiation Dynamic Study of the Phenomenon of (M. Thiery and R. G J Willighagen), 1243
Enzymatic Determination in Serum of Lathyritic and Prednisone-treated Lathyritic Rats (Prof. G W Korting, H Holzmann and B. Morsches), 1130
Enzyme and Catechol-*O*-methyl Transferase Activity in Normal and Leukaemic White Blood Cells : Methionine-activating (Dr R. J Baldessarini and Dr. W. R. Bell), 78
Enzyme-elevating Virus on Tumour-bearing Mice : Action of Riley's (Dr. A. Georgii *et al.*), 929
Enzyme Reaction : Highly Damped Oscillations in a Peroxidase-like (Prof E H Strickland and Prof. E. Ackerman), 405
Enzyme Reaction : Oscillation in (Prof C. Walter), 404
Enzyme Syntheses in Bacteria : Entrainment Model for Timed (Dr B. C. Goodwin), 479–81
Enzyme Synthesis in *Bacillus subtilis* · Repression and the Control of Cyclic (Dr. M. Masters and Dr. W D. Donachie), 476–9
Enzyme System in the Alga *Prototheca zopfii* : Adaptive Butyrase (Dr. D R. Cullimore), 531
Enzymes of *Citellus citellus* and *Spalax leucodon* · Proteolytic (M. I Jankovič *et al*), 316
Enzymes : Introduction to the Study of (Dr. H. Gutfreund), *review* by Dr K. Dalziel), 335
Enzymes in Normal and Leukaemic Human Leucocytes : Distribution Patterns of Proteolytic (Prof. R. J Haschen and Dr. K Krug), 511
Enzymes in White Muscle Disease : Activity of Lysosomal (Dr. I. D. Desai), 1349
Ephestia kuhniella Z. *in vitro* : Effect of Zinc Ions on Mitosis in Wing Anlagen of (Dr. C A. Barlow), 1045
Epidermal Keratin Synthesis · Intracellular Site of (Dr. G. C. Priestley and Dr. P. T. Speakman), 1336
Epidermal Melanin Unit : Vertebrate (M. E. Hadley and W. C. Quevedo, jun.), 1334
Epidermis of the Sheep . Branched Cells in the (Dr A. G. Lyne and Prof. H. B. Chase), 1357
Epididymal Spermatozoon : Presence of Sodium-Potassium-stimulated ATPase in Boar (S. Uesugi and S. Yamazoe), 403
Epileptiform Seizures induced by Hypothalamic Stimulation in the Rat · Resistance to Fits following Fits, (Dr. L. J. Herberg and P. J Watkins), 515
Episome-determined Protein Antigen of *Escherichia coli* . K88, an (Dr. S. Stirm *et al*), 507
Epitaxial Deposition of Cadmium Selenide (A. Brunnschweiler), 493
Epoxides and their Derivatives (M. N. Malinovskii), *review* by Dr. J. Biggs, 335
Equality and Power (R V. Sampson), *review* by T H. Hawkins, 1167
Equation useful for fitting Survival Curves of X-ray Irradiated Protozoa . an Alternative Multi-target (Dr. J. Calkins), 172
Equilibria among Oxides in Steelmaking : Phase (Prof. A. Muan and Prof. E. F. Osborn), *review* by Dr. D. S. Oliver, 845
Equilibrium at the Solid-Liquid Interface (Prof. W. J. Heideger and A. Vasudev), 295
Equipment for the Services : Electrical and Electronic, *review*, 645–7
Eruption of March 1962 reaches New Zealand . Pumice from the South Sandwich (Prof. D. S. Coombs and C. A. Landis), 289
'Erythroblastosis Foetalis' in the Primate, *Tamarinus nigricollis* (Dr. N Gengozian, C. C Lushbaugh, G. L. Humason and Dr R. M. Kniseley), 731
Erythrocyte Ghosts : Formation of Adenosine Triphosphate by Human (G. Ronquist and Prof. G. Ågren), 1090
Erythrocyte Glucose-6-Phosphate Dehydrogenase Activity in Haemoglobin H Disease (Dr. T. K. Chan, Dr D. Todd and Dr C C Wong), 1147
Erythrocyte Groups in Human Histocompatability Reactions : Role of ABO (Prof. J. Dausset and Dr. F T. Rapaport), 209
Erythrocyte Nucleoproteins : Calf Thymus and Chicken (M. Champagne and A. Mazen), 1131
Erythroid Activity of the Bone Marrow on the Plasma Disappearance of Injected Erythropoietin in Dogs : Influence of the (C E. Bozzini), 1140
Erythropoiesis stimulated by Phenyl-hydrazine : Effect of (J. Manis and Prof. D. Schachter), 1356
Erythropoietin in Dogs : Influence of the Erythroid Activity of the Bone Marrow on the Plasma Disappearance of Injected (C. E. Bozzini), 1140
Esau, Prof Katherine : Plant Anatomy, Second Edition, *review* by Dr. A. Allsopp, 443
Escherichia coli : Isolation of the Permease Expression of the *LAC* Operon of (Dr A. R. Kolber and Dr. W D Stein), 691–4
K88, an Episome-determined Protein Antigen of (Dr. S. Stirm *et al.*), 507
Sensitization of, to Radiation by Bromouracil (Dr. S. Aoki *et al*), 686–8
Stability of β-Galactosidase in Starved (R. E. Strange), 428
Escherichia coli exposed to Ultra-violet Light : Production of Additional Sites of Deoxyribonucleic Acid Breakdown in Bromouracil containing (Prof. R. P. Boyce), 688–91
Eskimo Administration, 562

Ethanol by the Isolated Perfused Rat Liver : Effect of Aeration on the Consumption of (E. R. Gordon), 1028
Ethionine-induced Hypoglycaemia (Prof. B Combes and S. Schenker), 911
Ethyl Alcohol-Water Mixtures : Anomalies in Contact Angle Behaviour for (A B. Ponter *et al.*), 504
Ethylenediamine Tetraacetic Acid in the Cow and Goat : Intravenous Infusions of Calcium and (Dr. L. M. Sherwood *et al*), 52
Ethyleneimine Hydrolysis of Di(aziridin-1-yl)Sulphoxide to (Dr. R M. V. James), 518
Ethyl Esters of Fatty Acids by the Lactating Goat : Conversion of Alcohol to (Prof S Patton and Dr. R D McCarthy), 616
N-Ethylmaleimide and Di-*t*-butyl Nitroxide Radiosensitizers towards HeLa S 3 Cells in a Single Cell Culture. Toxicity of (M. Klimek), 1256
Ethyl Methane Sulphonate . Mutants of *Puccinia graminis avenae* induced by (Dr. E P. Baker and C Teo,)632
Europe . Oil and Gas Pipelines in, 1288
European Journal of Cancer (D. A Brunning), 668
European Mid-Devonian Correlations (Dr. P Copper), 982–4
European Molecular Biology Organization (EMBO) Grants, 456
Europium (II) in Aqueous Perchloric Acid Solutions : Electron-transfer Reactions of (A Adin and Dr. A. G Sykes), 804
Evans, Dr. A M., Garrett, P, and Whitaker, J. H. McD. : Palaeocurrents in the Upper Cambrian of North Wales, 1230
Evans, Dr. E. Anthony : Control of Self-irradiation Decomposition of Tritium-labelled Compounds at High Specific Activity, 169–71
Stability of a Radio-active Drug—Tetrasodium 2-Methyl-1, 4-napthaquinol Diphosphate labelled with Tritium, 196
Evans, J. A , and Crowley, J P · Haemoglobin Typing of the Kerry Breed of Cattle, 309
Evans, P K., *et al.* : Changes in Mititoc Activity during Early Callus Development 1115
Evoked Potentials correlated with a Visual Anomaly (Prof. D. M. MacKay and Dr. A. Fiorentini), 787–9
Evolution of Genetics (A. W. Ravin), *review* by Prof. J. M. Thoday), 747
Evolution of Mathematical Thought (Prof. H. Meschkowski), *review* by Prof. T A. A. Broadbent, 235
Evolution of Over-dominance during the Initial Spread of New Alleles (S. K. Jain), 429
Evolution : Possible Importance of Transfer Factors in Bacterial (Dr. E. S Anderson), 637
Evolving Genes and Proteins (edited by V. Bryson and H. J Vogel), Symposium, 1964, *review* by Dr. B F. C. Clark, 747
Examinations . 'O'-Level, 460
Exchange Scheme between Britain and India for Younger Scientists, 665
Excimer X-ray Investigation (Dr L. G. Christophorou and J. G Carter), 678–80
Excitatory Action of Prostaglandin E_1 on Brain-stem Neurones (Dr. G. L. Avanzino *et al.*),87

Excretion of Acetylsalicylic Acid in Man Urinary (A. J. Cummings and M L. King), 620
Excretion of the 'Milk Toxin' : Metabolism of Aflatoxin in Sheep : (Dr. R.Allcroft et *al*), 154
Excretion in the Rat : Cyanide (Dr. A. D. M. Smith and M. Foulkes), 919
Expansion of Rubidium Dihydrogen Phosphate : Thermal (Dr. V. T. Deshpande and A. A. Khan), 608
Expedition : 1964–65 Belgian Trans-Saharan (Prof. J. Léonard), 126
Experience : The Brain and the Unity of Conscious (Sir John Eccles), *review* by Prof W. H. Thorpe, 1274
Experiments in Plant Hybridization (G. Mendel), *review* by Prof J. M. Thoday, 1061
Exploding Wires : Hard X-rays from (Prof. S. K. Handel *et al.*), 1227
Exploration of a Simple Maze : Effect of Previous Exploratory Activity on the (M. S. Halliday), 432
Exploratory Activity on the Exploration of a Simple Maze · Effect of Previous (M. S. Halliday), 432
Extension-growth and Regeneration in Horseradish : Correlation between Induced (Dr. J. Dore), 98
Extinction Coefficient of Water at 2.93 μ and Water Content of Black Foam Films (Dr. J. S. Clunie, Dr. J. F. Goodman and C. P. Ogden), 1192
Extinction Coefficients of some Muscle Nucleotides and Purines at *p*H 7.0 and in 2 N Hydrochloric Acid : Ultra-violet (P. W. Ratcliff and M. J. Follett), 1129
Extraction of some Physiologically Active Amines : Liquid Ion-exchange (Dr. D. M. Temple and R. Gillespie), 714
Eye for Isotopes, 23
Eye Movements during Inattention : Fine (Dr K. Gaarder), 83

Facies Relationships : Depositional Environment of British Liassic Ironstones considered in the Context of their (Dr A. Hallam), 1306–9
Factors Controlling the Secretion of Parathyroid Hormone : Evaluation by Radioimmunoassay of (Dr. L. M Sherwood *et al*), 52
Faeroes : New Data on the Geological Age of the (J. Rasmussen and Prof. A Noe-Nygaard), 1229
Falk, J. E. · Baas Becking Biogeological Research Laboratory, Canberra, Australia, 669
Fallow Deer Uncertainty of Leadership-rank in (B. K. Gilbert and Dr. J. P. Hailman), 1041
Faraday Effect in Haemoglobin and Myoglobin : Anomalous Dispersion of the (Prof M. V. Volkenstein, J. A. Sharonov and A. K Shemelin), 709
Farm Animals : Energy Exchange in : *review* on Energy Metabolism by Dr. M. Silver, 1165
Farmer, C. B., and Houghton, Dr. J T. : Collision-induced Absorption in the Earth's Atmosphere, 1341
Farrow, John T., *et al.* : Transfer of Conditioned Responses from Trained Rats to Untrained Rats by means of a Brain Extract, 46–8
Fasciola hepatica · Collagenase Activity of Immature (Dr R. M. Howell), 713 Some Apparent Effects of Bithionol ('Actamer') on (Prof B. Dawes), 424
Fast Reactor Agreement between Japan and Britain, 135
Fat . Localization of Catecholamines in Brown ([The late] Dr. M. J. R. Dawkins *et al*), 1144
Fatigue of β-Brass Crack Initiation during the (H. Mcl Clark), 193
Fatigue of Metals : Enhanced Diffusion Rates during the (Dr. W. J. Derrick Jones and W D Dover), 704
Fatigue . Strain Hardening in (Dr A T Price and P. J. Smith), 1123
Fatty-Acid Activation in Rat Liver Mitochondria Organization of (D. W. Yates, D Shepherd and Dr P B. Garland), 1213–5
Fatty Acid and Blood Glucose-levels · Effects of Synthetic Angiotensin on Plasma Free (Prof J. Nakano and T. Kusakari), 922
Fatty Acid Composition of Triglycerides from Adipose Tissue ([The late] Dr. M. J R. Dawkins and J. F Stevens), 1145
Fatty Acids by the Lactating Goat . Conversion of Alcohol to Ethyl Esters of (Prof. S. Patton and Dr. R. D McCarthy), 616
Fatty Acids and Paraffins in Some Lower Cretaceous Sediments Molecular Distributions of Normal (K. A. Kvenvolden), 573–7
Fay, Dr. P , and Walsby, A. E. : Metabolic Activities of Isolated Heterocysts of the Blue-green Alga *Anabaena cylindrica*, 94

Hydrogen : Stereospecific Catalytic Labelling of Amino-acids and Mandelic Acid with Isotopic (G E. Calf *et al.*), 502
Hydrogen : Thermoelectric Power and Chemisorbed (Prof. D. D. Eley and J. Petro), 501
Hydrogen Peroxide : Liberation of Adenine from Deoxyribonucleic Acid by (Prof. K. Yamafuji and Dr Y. Uchida), 301
Hydrolysate of Melanosomes from Harding-Passey Mouse Melanoma : Large Amounts of Deoxyphenylalanine in the (Dr. H. Takahashi and Prof. T. B. Fitzpatrick), 888–90
Hydrolysis of Di (aziridin-1-yl)sulphoxide to Ethyleneimine (Dr R. M. V. James), 518
Hydrostatic Pressure in a Sea Anemone : Continuous Recording of the (E. R. Trueman), 830
α-Hydroxybutyric Dehydrogenase Activity of Human Vascular Tissue (R. Sanwald and Prof. J. E. Kirk), 912
N-Hydroxy-2-fluorenylbenzamide, an Arylhydroxamic Acid with High Carcinogenic Activity (Prof. H. R. Gutmann, S B Galitski and W. A Foley), 202
γ-Hydroxynorvaline from *Lathyrus odoratus* Seed : Isolation of (Prof. L. Fowden), 807
20α-Hydroxypregn-4-ene-3-one and 20β-Hydroxypregn-4-ene-3-one : Maintenance of Pregnancy in Spayed Rats with (Dr P. K Talwalker *et al.*), 86
Hyperbaric Oxygen : Regulation of Cellular Autolysis by (Dr R. M. Rosenbaum *et al.*), 895
Hyperbaric Oxygenation · Proceedings of Second International Congress, 1964 (edited by I McA. Ledingham), *review* by Prof. R. E. Coupland, 949
Hyperchondroplasia Induced by Crude Papain administered to Mice : Localized (Prof. H. K. Suzuki), 1111–3
Hyperplasias in Mice : Nucleic Acids of Malignant and Benign Splenic (L. Kravetz de Srulijes *et al*), 1038
Hyperpolarization in Stretch Receptor Neurone of Crayfish : Post-tetanic (Dr. S Nakajima and Dr K. Takahashi), 1220
Hypersonic Aerodynamics · Elements of (Dr. R. N. Cox and Dr. L. F. Crabtree), *review* by Prof A D Young, 1163
Hyperthyroid Mice Paradoxical Effect of Dichloroisoproterenol on Pentobarbital Sleep Time in (E H Ellinwood, jun.), 1250
Hyperuricaemia · Renal Handling of Glycine in Primary (Prof. David Kaplan *et al.*), 213
Hypervitaminosis A · Lipid Metabolism in (U. K Misra), 910
Hypocuprosis of Cattle in the Argentine (J. B. Bingley and B. J. Carrillo), 834
Hypoglycaemia : Ethionine-induced (Prof. B. Combes and S. Schenker), 911
Hypophysectomized Killifish, *Fundulus heteroclitus*, in Freshwater : Prolactin and Serum Osmolality of (Prof. G. E. Pickford *et al*), 1040
Hypophysectomized Mice : Effect of Gonadotrophins on Uterine Growth of (Dr. D R Lamond and B M. Bindon), 512
Hypophysectomized and Thyroxine-treated Rats : Accumulation of Excessive Doses of Iodide by the Thyroid Gland of Normal, (Dr I Posner and Dr. E. Pimentel), 514
Hypophysectomy of the Rat · Impaired Ability of Ribosomes to react with Polyuridylic Acid after (Dr. A. Korner and J. M. Gumbley), 505
Hypothalamic Stimulation in the Rat : Epileptiform Seizures induced by (Dr L J. Herberg and P. J. Watkins), 515
Hypothalamic Temperature-sensitive Cells : Behavioural Significance of (Dr. H J Carlisle), 1324
Hypothermia in Youth : Clothing Insulation and Accidental (L. G. C. Pugh), 1281–6
Hypothesis for the α-Chains of Tropocollagen : 3,2,1 : *A,B,C* Sub-unit (Prof. P. M. Gallop), 73
Hypothymism? Is Hodgkin's Disease a Syndrome of (Dr. G. J. Svet-Moldavsky), 932
Hypoxia *In vitro* Oxygen Consumption of Slices from Kidney, Brain, Cortex and Liver in (J. Skolnik *et al.*), 305
Hysteresis in the Flow through an Orifice (B. E. L. Deckker), 604

Iball, Dr. J., Morgan, Dr. C. H., and Wilson, Dr. H. R. : Structures of 5-Bromodeoxyuridine and 5-Bromouridine, 1230–2

Ice : New Structure in the Electron Spin Resonance Spectrum of γ-irradiated Single Crystals of (G. H. Dibdin), 394
Iceland Hot Springs : Temperature Optima for Algal Development in Yellowstone and (Prof. T. D. Brock and Mrs. M. L. Brock), 733
Identification of Poliovirus from a Clinical Specimen : Isolation and (Dr. A. Hellman and Prof. D J. Giron), 324
IgA : Sensitization of Mice with Human (Prof. L. S. Kind), 926
Igast Objects : Terrestrial Origin of the (Dr. P. D. Lowman, jun., and Dr. J. A. O'Keefe), 67
Ikuma, Dr. Hiroshi, *et al.* : Near Ultra-violet Spectrum of White Potato Mitochondria, 174
Illusions : Optical (Dr. G. K. Wallace), 327; (Dr. R. L. Gregory), 327
Illusion and a Confusion Theory Explanation : Muller-Lyer Haptic (A. Watson and C. French), 942
Immiscible Liquids Propagation of Stress Pulses across the Interface between Two (Dr. D. H. Trevena), 289
Immune Depression and Runting in Neonatally Thymectomized Mice : Sex Difference for (Dr. H. Balner and H. Dersjant), 815
Immune Globulins of Various Vertebrate Classes : Comparative Investigation of (Prof. H. Ambrosius), 524
'Immune' Lymphoid Cells in Diffusion Chambers : Failure to transfer Sensitivity to Skin Homografts by Means of (Prof. D. B. Wilson *et al.*), 1359
Immune Lymphoid Cells : Inhibitory Effect of Carcinostatic Agents on Anti-tumour Activity of (Dr. Y. Hashimoto *et al.*), 1360
Immune Response : Cortisol and the (Dr. G. L. Sorem and Prof. G. Terres), 1254
Immunity to Friend Virus Disease · Passive and Active (Prof. E. A. Mirand, Dr. J. T. Grace, jun., and R. F. Buffett), 696–8
Immunity with Tumour Cells treated with Iodoacetate : Induction of Tumour (Dr. C. A. Apffel *et al.*), 694–6
Immunization of Mice with Chagastoxin : Active (Dr. H. Seneca, P. Peer and B. Hampar), 309
Immunization with Protein-Cellulose Copolymer (Immunosorbent) (A. M. Olovnikov and A. E. Gurvich), 417
Immunized Young *NZB* Mice Increased Red Cell Breakdown in Adoptively (Dr. R. D S. Barnes and M. Tuffrey), 1095–9
Immuno-adsorbents of High Capacity (J. C. Metcalfe, H. F. Marlow and Prof. A. S. V., Burgen), 1142
Immunochemical Properties of Nucleoproteins : Antigenic Characteristics of DNA Protein from a Canine Haemangiopericytoma : Comparative (Prof. R. H. Wilson, V. Jurevics, R. Delaney, T. Ritter, K. Rencz and A. Schram), 1102–5
Immunoelectrophoretic Examination of Avian Serum Esterases (M. Kaminski), 723
Immunoelectrophoretic Properties of Low-density Human Serum Lipoproteins (Prof. F. Aladjem), 1003–5
Immunoglobulins : Notation for Genetic Factors of Human, 653–5
Immunological Tolerance of Neonatally Infected Mice to the Moloney Leukaemia Virus (E. Klein and G. Klein), 163
Immunological Tolerance as the Result of Terminal Differentiation of Immunologically Competent Cells (Dr. J. Šterzl), 416
Immunologically Activated Cells : Radiosensitivity of (Dr. M. C. Berenbaum), 1313–5
Immunologically Competent Cells : Immunological Tolerance as the Result of Terminal Differentiation of (Dr. J. Šterzl), 416
(Immunosorbent) : Immunization with Protein-Cellulose Copolymer (A. M. Olovnikov and A. E. Gurvich), 417
Impact of Plasma on a Dipole Magnetic Field (Dr. J. B. G. Roberts and J. P. Turner), 755–7
Impact of Science on Society, 1178
Impact of Society on Science : Presidential Report to Carnegie Institution of Washington, 1964–1965, *review*, 743–5
Impact Testing of Zircaloy : Instrumented (G. D. Fearnehough), 392
Imperial College of Science and Technology, London : New Biochemistry Building (Dr. R Thomas), 444
Importance of Technology (Prof. J. K. Feibleman), 122
Impulse Origin and Conduction in the Mammalian Heart : Nature of (Prof. B. F Hoffman and Prof. P. F. Cranefield; Dr. C. J. G. Wensing), 1107–9
Impure Argon : Ionization Relaxation in Slightly (Dr. N. R. Jones and Dr. M. McChesney), 1080
Impurity on Thin Foils of Ferrous Materials : Detection of Magnetite as a Surface (D. J. Dyson and S. R. Keown), 707
Inactivation and Induction of Electron Spin Resonance-centres in Trypsin by Ionizing Radiation and by Ultra-violet Light (T Brustad), 31
Inattention : Fine Eye Movements during (Dr. K. Gaarder), 83
Incidence of *Atherigona indica infuscata* Emden Diptera (Anthomyiidae) on Sorghum due to Spraying : Increases in the (J. C. Davies and D. Jowett), 104
Incidence of Brown-spot Disease (*Helminthosporium oryzae* Breda de Haan) : Intervarietal Mixtures of Rice and (Prof. G. Grummer and Prof. S. K. Roy), 1265–7
Incompatability of Synthetic Tetracosa-peptide Corticotrophin with the present U.S.P. and International Corticotrophin Standard (Dr. C Rerup), 89
Incorporation in Isolated Rabbit Diaphragm . Effect of Vitamin E Deficiency on Uptake of Amino-acid and (Prof. J. F. Diehl), 75
Incorporation of Phosphorus-32 into the Alcohol-soluble Fractions of Pea Seedlings : Effect of Plant Regulators on the (Dr. E. Kóves and Dr. F. Sirokmán), 420
Increases in the Incidence of *Atherigona indica infuscata* Emden Diptera (Anthomyiidae) on Sorghum due to Spraying (J C. Davies and D. Jowett), 104
Incubated Fibrinogen : Variable and Invariable Components of the Anticoagulant Fraction of (Prof. E. Triantaphyllopoulos and Prof. D. C Triantaphyllopoulos, 265–7
Incubation, Calcium and Phosphate : Plaque Formation by Purified Salivary Mucin *in vitro* : Effects of (C. McGaughey and Dr. E. C. Stowell), 897–9
Incubation of Mouse Thymus Cells with Leukaemia Cell Nucleic Acid : Attempts to induce Leukaemia by (Dr. E. F. Hays), 1327–30
Incubation Temperature and of Storage on the Viability of Fungal Spores damaged by Phenol : Influence of (Dr. N. M. Chauhan *et al.*), 106
Indexes and Indexing, 762
India : Supply of Anti-serum in, 966
Aid to, 1288
India for Younger Scientists : Exchange Scheme between Britain and, 665
Indian Mica between 300 and 1,000 mμ and its Visual Classification : Transmission of (R. N. Dhar and S. R. Das), 185
Indians : Xg Blood Groups of American (W. Bouman *et al.*), 411
Indicator of Manganese-54 Contamination in Terrestrial Environments : Biological (R. Cavalloro and O. Ravera), 1259
Indo-Pacific Region : Distribution of the Genus *Nephrops* (Crustacea Decapoda Macrura) in the (A. J. Bruce), 535
Induction of Electron Spin Resonance-centres in Trypsin by Ionizing Radiation and by Ultra-violet Light : Inactivation and (T. Brustad), 31
'Inductor' for Bacterial Cell Differentiation : Sporogen—an (Prof. V .R. Srinivasan) 537
Industrial Research in Britain : Progress of, 458
Industry : Future of the British Aircraft, 1053–7
Industry and their Inter-relation . Research Facilities available to (A. C. Low and Dr. A. J. Rostron), 255
Infections of *Schistomsoa mansoni* and the Passive Transfer of Resistance : Reagin-like Antibodies in Experimental (Dr. B. M. Ogilvie *et al.*), 1221–3
Infectivity of Gross and Reuscher Leukaemia Viruses and their Nucleic Acids (Dr. E. F. Hays and F. F. Alpert), 1326
Influences on Measured Intelligence : Social (R. Weatherall), 1298–1300
Influenza Viruses by Horse Serum Inhibitor : Flocculation of (Dr. F. Biddle and Dr. J. P Stevenson), 1223–5
Information and Prediction in Science · Symposium, 1962 (edited by S. Dockx and P. Bernays), *review* by D. Miller), 1162
Information Processing, 1178
Infra-red : Decrement of the Solar Continuum in the Far (Dr. R. Beer), 1226
Infra-red Spectral Analysis of the Apoproteins of some Haemoglobins and Myoglobins (Prof. M. Z. Atassi and L. R. Cacciotti), 1211–3
Ingalls, Dr. R. B , *et al.* : Electron Spin Resonance Technique for Investigating Reactions of Free Radicals with Compounds of Biological Interest : Nucleic Acid Constituents, 1017
Ingle, H. D , and Davies, G. W. : Wall Thickening in *Callitris glauca* R. BR., 826
Ingold, Prof. C. T. : Spore Liberation, *review* by Prof. N. F. Robertson, 1165
Inhaled Particles and Vapours (Dr. C N. Davies), 24–27
Inhibitor : Flocculation of Influenza Viruses by Horse Serum (Dr. F. Biddle and Dr J P. Stevenson), 1223–5
Inner Ear in the Mammalian Embryo . Influence of the Neural Tube on the Differentiation of the (Dr M. S Deol), 219
Inoculation with Adenovirus 5 : Inhibition of Adenovirus 12 Oncogenicity in Hamsters by Simultaneous (J. Peries *et al.*), 738
Inorganic Chemistry : Vol. 4 : Technique of (edited by Prof. H. B. Jonassen and A. Weissberger), *review* by K. W. Bagnall, 121
Inorganic Compounds : Free Energy Functions and Deviations in Thermochemical Data Storage for (Prof. C. B Alcock), 198
Insect Behaviour (Dr. P. T. Haskell), 145
Insect Central Nervous System : Physiology of the (edited by J. E. Treherne and J W. L. Beament), *review* by Prof. L. H. Finlayson, 546
Insect Control · New Perspectives in, 1179
Insecticide Chemicals and Pharmaceutical Alkaloids on Thin-layer Chromatograms : Detection of Cholinesterase-inhibiting (Dr. J. J. Menn and J. B, McBain), 1351
Insecticide Selections in *Tetranychus urticae* Koch (Acari : Tetranychidae) : Intersterility as a Consequence of (W. P. J. Overmeer), 321
Insects : Depressant Effect of Moonlight on Activity of Aquatic (Prof. N. H. Anderson), 319
Forest Diseases and, 859
Plastron Respiration in Marine (Prof. H. E. Hinton), 220
Instability of some of the Products formed by the Action of *N*-Methyl-*N*-nitrosourethane on Cysteine *in vitro*. Role of Neighbouring Groups in Enzymatic and Carcinogenic Action (Dr. R Schoental), 148
Institute of Actuaries : Election of Officers 1966–67, 1180
Institute of Mathematics and its Applications : Election of Sir Geoffrey Taylor as First Honorary Fellow, 760
Institute of Mechanical Engineers : James Clayton Fellowship, 353
Presidential Address : *Ex Opera et Industria*, 561
Institute of Physics and the Physical Society : Appointments and Awards, 1180
Institute of Technology . Bradford, Appointments, 1291
Institute of Technology : New Center for the Life Sciences at the Massachusetts (Prof. I W. Sizer), 852
Instrumentation with Semiconductors for Medical Researchers (Prof. C. C. Brown and G. N Webb), *review* by Dr. J. R. B Greer, 333
Instrumented Impact Testing of Zircaloy (G D. Fearnehough), 392
Insulation and Accidental Hypothermia in Youth : Clothing (L. G. C. Pugh), 1281–6
Insulin and Glucagon : Possible Structural Similarity between (T. M. Schuster), 302
Insulin : Incorporation of ^{35}S-methionine into (S. A. Morenkova), 917
Intelligence . Social Influences on Measured (R. Weatherall), 1298–1300
Intensities of the Next Two Sunspot Maxima : Prediction of the Dates and (D. G. King-Hele), 285
Intensity Distribution of the Lyman-Birge-Hopfield Band System of N_2 (D. J. McEwen and Prof F. W. Nicholls), 902
Intensive Livestock Husbandry, 331
Inter-breed, Intra-breed and Autoplastic Chimerae of the Domestic Fowl (P. N. Martinovitch, M. R.-Pavlović-Hournac and J. V. Martinovitch), 816
Intercellular Communication and the Control of Tissue Growth : Lack of Communication between Cancer Cells (Prof. W. R. Loewenstein and Dr. Y. Kanno), 1248
Intercellular Space in Normal Human Stratum Corneum (Dr. I Brody), 472–6
Interface between Two Immiscible Liquids : Propagation of Stress Pulses across the (Dr. D. H Trevena), 289
Interface Equilibrium at the Solid-Liquid (Prof. W. J. Heideger and A. Vasudev), 295
Interfaces : Monolayers at Liquid (Dr. D. A. Haydon and M. J. Jaycock), 565
Interferometer at the Royal Radar Establishment · Positions of Radio Sources determined by the (R. L. Adgie and H Gent), 549–51
Interferometry by Wavefront Reconstruction : Dual- and Multiple-beam (Dr. J. M. Burch, A. E. Ennos and R. J. Wilton), 1015
Interhemispheric Communication in Monkeys (*Macaca mulatta*) : Cortical Lesions and (C R Butler), 59
Intermittent Light : Stability of Adaptation of Critical Flicker Fusion Frequency to (Dr. P. Turner *et al*), 813
International Clearing House for Medical Terminology and Medical Lexicography, 456
International Commission on Zoological Nomenclature, 1179
International Encyclopedia of Science (edited by J. R. Newman), Four Volumes, *review* by Dr W L. Sumner, 546
International Geophysical Calendar for 1966, 16
Interoceptive Conditional Response in Cortical Neurones (G. Adám, Prof. W. R. Adey and Prof. R. W Porter), 920
Interphase Death and Related Biochemical Radiation Effects in Murine Leukaemia Cells (Dr. H. M. Bouwen, A. W. M. Appelman and M. J. de Vries), 1149
Interphase Nucleus : Kinetics of Two-break Chromosome Exchanges and the Spatial Arrangement of Chromosome Strands in (Dr. Sushil Kumar and Dr A. T. Natarajan), 796
Interplanetary Medium : Measurements of the Size and Motion of the Irregularities in the (Dr. A. Hewish *et al*), 1188
Interstellar Grains and the Diffuse Galactic Light (R. D. Wolstencroft and L. J. Rose), 388
Intersterility as a Consequence of Insecticide Selections in *Tetranychus urticae* Koch (Acari : Tetranychidae) (W. P J Overmeer), 321
Interstitial Atoms on a Lattice-vacancy Diffusional Process : Effect of (G. A, Davies, A. B. Ponter and Dr. I. A. Menzies), 1125

Intervarietal Mixtures of Rice and Incidence of Brown-spot Disease (*Helminthosporium oryzae* Breda de Haan) (Prof. G. Grummer and Prof. Subodh Kumar Roy), 1265–7
Intestinal Absorption of Pralidoxime and other Aldoximes (Prof. R. R. Levine and Dr. G. M. Steinberg), 269–71
Intestinal Bacteria . Effect of Antibiotics on Some Rumen and (I. El Akkad and Dr. P. N Hobson), 1046
Intestinal Epithelial Cells : Active Transport of Glucose by Suspensions of Isolated Rat (Dr. B K. Stern and Dr. W. E. Jensen), 789
Intestinal Microfloras based on Investigations on *Bibio marci* (Diptera) Larvae : Problem of Absolute and Relative Specificity of (I Szabó and M. Marton), 221
Intestinal Transfer · Polyphenolic Compounds and (D. W. Hand *et al*), 618
Intestine : Histochemical Demonstration of the Resorption of Xylose from Small (D. Stiller), 924
Intestine during Pregnancy : Increased Active Transport of Glucose through the (Prof J. Larralde *et al.*), 1356
Intestine : Active Transport of Iron by (J. Manis and Prof. D. Schachter), 1356
Intra-breed and Autoplastic Chimerae of the Domestic Fowl : Inter-breed, (P. N. Martinovitch *et al.*), 816
Intracellular Distribution of the Different Forms of Lactic Dehydrogenase (Dr. A. Agostoni, C. Vergani and L Villa), 1024
Intracellular Membraneous Structure Symposium 1963 (edited by S. Seno and E. V. Cowdry), *review* by Dr. J. A. Armstrong, 336
Intracellular Oxidation-reduction State : Ionizing Radiation and the (D. Jamieson), 361–5
Intra-cellular Site of Epidermal Keratin Synthesis (Dr. G. C. Priestley and Dr. P. T. Speakman), 1336
Intranuclear Structures in Neurones (Dr. R. L. Chandler), 1260
Intraretinal Discrimination of Horizontal and Vertical Planes of Polarized Light by Octopus (Prof. K. Tasaki and Prof K. Karita), 934
Intravenous Infusions of Calcium and Ethylenediamine Tetraacetic Acid in the Cow and Goat (Dr. L. M. Sherwood *et al.*), 52
Intravenous Lidocaine Blocking of Cortical Inhibitory Synapses by (Prof. K. Tanaka and Dr. M Yamasaki), 207
Introduction to the Study of Enzymes (Dr. H. Gutfreund), *review* by Dr. K. Dalziel, 335
Inventor and his Patent . Patent Protection (C. Lees), *review* by Dr. B. J. A. Bard, 1057
Investment Proposals and Decisions (Prof. B. R. Williams and W. P. Scott), *review* by T. H. Hawkins, 1060
Iodide by the Thyroid Gland of Normal, Hypophysectomized and Thyroxine-treated Rats : Accumulation of Excessive Doses of (Dr. I. Posner and Dr. E. Pimentel), 514
Iodides : Primary Process in the Photolysis of Alkyl (R. J. Donovan and Dr. D. Husain), 609
Selective Herbicidal Activity of (Prof R. L. Wain *et al*), 98
Iodine-131-labelled Ceruloplasmin in Human Beings : Turnover of (M. Kekki *et al*), 1252
Iodine-131 and Circulating Iodine Compounds : Influence of Cold on Thyroid Uptake of (Dr J. P. Salvaneschi *et al*), 1240
Iodoacetate · Induction of Tumour Immunity with Tumour Cells treated with (Dr C. A. Apffel *et al*), 694–6
Iododeoxyuridine into Tumour DNA *in vivo* when coupled to Polycation : Increased Localization and Incorporation of (Dr. R. J. Woodman), 1362
Ion-exchange Chromatography · Isolation of Ammonium Thiophosphite by means of Preparative ([The late] Dr F. H Pollard *et al*), 396
Ion-exchange Column Method for the Estimation of Cystine and Methionine : Short (Prof O. A M. Lewis), 1239
Ion-exchange Extraction of some Physiologically Active Amines : Liquid (Dr. D. M. Temple and R Gillespie), 714
Ion-exchange Phenomena in Phospholipid Mono-molecular Films : Demonstration of (E. Rojas, Dr. J. Y Lettvin and W F. Pickard), 886
Ion Separation in Bursting Air Bubbles An Explanation for the Irregular Ion Ratios in Atmospheric Precipitations (Dr. M. R. Bloch, D. Kaplan, V. Kertes and J Schnerb), 802
Ion Transport Mechanisms . Efficiency of (Prof N. R. Joseph), 398
Ion Transport in Plant Roots : Oligomycin Inhibition of (Prof. T. K. Hodges), 425
Ionic Phosphate Diffusion in the Soil on the Growth of *Hormidium flaccidum* : Influence of (Dr. D R. Cullimore), 326
Ionization Gauge : Measuring the Density and Direction of Molecular Flow in High Vacuum using an (L. Holland and C. Priestland), 274–6
Ionization in the Polymorphism of a Phospholipid · Evidence for the Involvement of (Dr J J Wren and D. S Merryfield), 1315–7
Ionization Relaxation in Slightly Impure Argon (Dr. N. R. Jones and Dr. M. McChesney), 1080
Ionizing Radiation : Chemical Protection against (Prof. Z. M. Bacq), *review* by J. H. Barnes, 547
Ionizing Radiation Induction of Chromosome Injuries in Mouse Bone Marrow under the Distant Effect of (N. F. Barakina and M. I. Yanushevskaya), 823
Ionizing Radiation and the Intracellular Oxidation-reduction State (D. Jamieson), 361–5
Ionizing Radiation and by Ultra-violet Light : Inactivation and Induction of Electron Spin Resonance-centres in Trypsin by (Tor Brūstad), 31
Iontophoretically Applied Drugs . Responses of Thalamic Neurones to (I. McCance *et al.*), 715
Iron by Intestine . Active Transport of (J. Manis and Prof. D. Schachter), 1356
Iron . New Methods of identifying Serum Siderophilin using Radioactive (S. Slopek *et al*), 1036
Ironstones considered in the Context of their Facies Relationships . Depositional Environment of British Liassic (Dr A. Hallam), 1306–9
Irradiated Protozoa : An Alternative Multi-target Equation useful for fitting Survival Curves of X-ray (Dr. J. Calkins), 172
Irradiated Rat Thymocytes : Factors influencing the Staining of Histones in (Dr. J. F Whitfield and Dr. T. Youdale), 730
Irradiated Single Crystals of Succinic Acid Stereospecific Addition of Hydrogen to Fumaric Acid in (Prof. I. Miyagawa and K. Itoh), 504
Irradiation · Collapse of Polyacrylamide Molecules on Electron (D. V. Quayle), 803
Irregularities in the Interplanetary Medium : Measurements of the Size and Motion of the (Dr. A Hewish, P. A Dennison and Dr. J. D. H. Pilkington), 1188
Ishidate, Prof. Morizo, *et al.* : Inhibitory Effect of Carcinostatic Agents on Anti-tumour Activity of Immune Lymphoid Cells, 1360
Isoamylases on Cellulose Acetate : Separation of Urinary (Dr. S. E. Aw), 298
Iso-antigens Mouse Thymic, 521
Mouse Nervous Tissue (Prof. A. E Reif and Dr. J. M. Allen), 523
Isoenzymes in Malignant Tissues · Lactate Dehydrogenase (Dr. H. Poznanska-Linde *et al*), 727
Isoenzyme Pattern in Human Myopathies : Abnormal (A. M. Katz and Prof. W. Kalow), 1349
Isohaemagglutinins in the Marmoset, *Tamarinus nigricollis* : Formation of (Dr. N. Gengozian), 722
Isolation and Identification of Poliovirus from a Clinical Specimen (Dr. A. Hellman and Prof. D. J. Giron), 324
Isolation of 'Protoplasts' from Fungal Mycelium : Use of Lipase and Strepzyme for the (I. G. Acha *et al*), 95
Isolation of Unstable Halogen Radical Ions : Matrix (D. M. Brown and Prof. F. D Daunton), 195
Isotherms and the Mixed Second Virial Coefficient : Partition (Dr. G. F Free-guard), 1124
Isotope Effects : Proton Transfer Processes in Muscle : Pressure, Temperature and (Dr R. A. Horne and D S. Johnson), 82
Isotopes : *Eye for*, 23
Isotopic Targets and Foils · Preparation and Standardization of (Dr. M. L. Smith), 142
Israel, Prof. Werner : Radial Motion in the Schwarzschild Field and the Issue of Gravitational Collapse, 66
Italy : Historical Marine Levels in (Dr. C. Vita-Finzi), 906
Itoh, Koichi, and Miyagawa, Prof. I. : Stereospecific Addition of Hydrogen to Fumaric Acid in Irradiated Single Crystals of Succinic Acid, 504
Itzhaki, Dr. S : Fundamental Cancer Research, 257
Ivy-leaf Sport in Potatoes : Periclinal Nature of the (Dr. H. W. Howard), 108

Menn, Dr. J. J., and McBain, J. B : Detection of Cholinesterase-inhibiting Insecticide Chemicals and Pharmaceutical Alkaloids on Thin-layer Chromatograms, 1351
Mental Health in a Changing World (edited by K. Soddy and R. H. Ahrenfeldt and M. C. Kidson) Vol. I, *review* by Dr. C Allen, 119
Mental Health : Research in, 1288
Menzel, Prof. D H., *et al.* : Detection of Hydrogen Emission Lines $n_{159} \rightarrow n_{158}$ and $n_{157} \rightarrow n_{156}$ in Galactic H II Regions, 468–70
Menzies, Dr. I A., *et al.* Effect of Interstitial Atoms on a Lattice-Vacancy Diffusional Process, 1125
Menzies, Dr. D. W. : Is there a Cortex-Medullary Cord Barrier in Lymph Nodes? 91
Mercuric Iodo-acetate in Glacial Acetic Acid and Its Reactions With Olefines : Formation of (T. D. Smith), 907
Mercuric Salts Synthesis of Alkyl-β-D-xylopyranosides in the Presence of (Dr. C. K. De Bruyne and Dr. F G Loontiens), 396
Mercury on Low-energy Solids : Contact Angles of (Dr. V. R. Gray), 608
Mercury : Possible Luminescence Effects on (D. P Cruikshank), 701
Meristic Variation in the Salamander *Ambystoma gracile* : Temperature-controlled (Prof. C. C. Lindsey), 1152
Merryfield, Danuta S., and Wren, Dr. J. J : Evidence for the Involvement of Ionization in the Polymorphism of a Phospholipid, 1315–7
Merz, Dr Timothy, Prempree, Dr. T , and Migeon, Dr. B. R : Thyroxin, Satellite Association and Trisomy, 1198–1200
Meschkowski, Prof. Herbert : Evolution of Mathematical Thought, *review* by Prof. T A. A Broadbent, 235
Meshii, M , *et al* (edited by) : Lattice Defects in Quenched Metals, *review* by Prof. C. R. Tottle, 648
Mesopic Photometry : A System of (Dr. D. A. Palmer), 276–81
Mestel, Prof. L. : Appointment to New Chair of Applied Mathematics in the University of Manchester, 965
Metabolic Activities of Isolated Heterocysts of the Blue-green Alga *Anabaena cylindrica* (Dr. P. Fay and A. E Walsby), 94
Metabolic Differences between Starch and Sucrose (S. Al-Nagdy, D. S. Miller, Dr. R. V. Qureshi and Prof. J. Yudkin), 81
Metabolism of Aflatoxin in Sheep : Excretion of the 'Milk Toxin' (Dr. R. Allcroft, H. Rogers, G Lewis, Dr. J Nabney and P. E Best), 154
Metabolism : Energy (edited by K. L Blaxter), *review* by Dr. M Silver, 1165
Metabolism of Gammexane in Flies, Ticks and Locusts (A. G. Clark *et al*), 103
Metal Complexes : Nitrogen-Fixation by Transition (Dr. M. E. Vol'pin and V. B. Shur), 1236
Metal Ions and Organic Solvents : Complex Formation between Transition (Prof. W. Lohmann *et al.*), 908
Metal Ions of the Racemization of the *Tris*-oxalato Chromium-III Anion : Catalysis by Alkali (J. A. Kernohan *et al*), 906
Metallurgy : Physical (edited by R. W. Cahn), *review* by Prof. J. J. Ball, 1163
Metallurgy : Theory of Transformations in Metals and Alloys : An Advanced Textbook in Physical (Dr. J. W. Christian), *review* by Prof. C. R. Tottle, 648
Metallurgy of Welding, Brazing and Soldering (J. F. Lancaster), *review* by Dr. R. G. Baker, 1058
Metals and Alloys · Theory of Transformations in (Dr. J. W. Christian), *review* by Prof. C R. Tottle, 648
Metals : Enhanced Diffusion Rates during the Fatigue of (Dr. W. J. Derrick Jones and W D Dover), 70–
Metals : Lattice Defects in Quenched (edited by R. M. J Cotterill *et al.*), *review* by Prof. C. R. Tottle, 648
Metamorphic Differentiation in Crenulated Schists (Dr. R. Nicholson), 68
Metcalfe, J C., Marlow, H. F., and Burgen, Prof A. S. V. . Immunoadsorbents of High Capacity, 1142
Meteorite Barwell, 247
Metepa, in *Aedes aegypti* Mosquitoes Resistance to a Chemosterilant, (W. Klassen and Prof F. Matsumura), 1155
Methicillin-resistant *Staphylococcus aureus* Penicillinase-negative Variants of (Dr S. J Seligman), 984–6
Methionine-activating Enzyme and Catechol-O-methyl Transferase Activity in Normal and Leukaemic White Blood Cells (Dr. R. J. Baldessarini and Dr. W. R Bell), 78
^{35}S-methionine into Insulin · Incorporation of (S A. Morenkova), 917
Methionine Short Ion-exchange Column Method for the Estimation of Cysteine and (Prof O. A M. Lewis), 1239
Method for identifying Small Amounts of Nitrosamines in Biological Material Dr W J Serfontein and P Hurter), 1238
Methotrexate-treated Rat : 9S and 7S Antibody Production in the *Cyclophosphamide*- or (Prof. G W. Santos and Dr A. H. Owens, jun.), 622
Methylcellulose to alter the Growth of Walker Tumour 256 in Rats : Failure of (Dr A. W Lazar, A Foth and D E. Lazar), 1140
Methyl Methacrylate . Effect of Zinc Chloride on the Velocity Coefficients in the Polymerization of (Prof C H. Bamford *et al*), 292
N-Methyl-*N*-nitroso-*N'*-nitroguanidine : Carcinogenic Activity of (Dr. R. Schoental), 726
N-Methyl-*N*-nitrosourethane on Cysteine *in vitro* . Instability of some of the Products formed by the Action of (Dr. R. Schoental), 148–51
Methylated Purines : Origin of Urinary (Dr. L. R. Mandel *et al.*), 586–8

Methylene Blue In Benzene : Absorption Spectra of (Prof. S. R. Palit and G. K. Saxena), 1127
Metoncholaimus SP. : Observations on the Bionomics of the Marine Nematode (B. E. Hopper and Prof. S. P. Meyers), 899
Metric Screw Threads, 20
Mexico : Scientists in, 1291

Mobility of Human Blood Platelets : Effect of Glass Contact on the Electrophoretic (Dr. J. R. Hampton and Dr. J. R. A. Mitchell), 470–2
Model of a Fracture Process : Monte Carlo (Prof. C. C. Harris), 1302
Model for Timed Enzyme Synthesis in Bacteria . Entrainment (Dr. B. C. Goodwin), 479–81
Modulation : Important Feature of Time (Dr. L. Molyneux), 188
Moisture Content by Neutron Scattering : Effect of Sample Density and Composition : Estimation of (E H. Waters and G. F. Moss), 287
Mole : Its Adaptation to Life Underground (V. C Barber), 971
Molecular Biology Organization Grants · European, 456
Molecular and Cellular Aspects of Development (edited by Dr. E Bell), *review* by Prof. O Lowenstein, 233
Molecular Dimensions and Crystal Structure of Dimethyl Sulphoxide at —60°C (Dr. M. A. Viswamitra and K. K. Kannan), 1016
Molecular Flow in High Vacuum using an Ionization Gauge : Measuring the Density and Direction of (L Holland and C. Priestland), 274–6
Molecular Orbital Calculations : Supplemental Tables of (Prof A. Streitwieser, jun , Prof. J. I. Brauman and Prof C. A. Coulson), Two Volumes, *review* by Prof. H. C Longuet-Higgins, 952
Molecular Sieve : Chromatographic Separation of Argon and Oxygen using (J. A. J. Walker), 197
Molecular Vibration · Odour and (R. H. Wright), 571–3
Molecular Weights of Prolactins and Pituitary Growth Hormones estimated by Gel Filtration (Dr. P. Andrews), 155–7
Molecules : Reactivity of Photo-excited Organic Molecules (Prof. A. R Ubbelohde), 28
Molgula manhattensis (De Kay) (Urochordata) : Protozoan Parasite of (C. H. Burren), 101
Molleson, Theya I., and Oakley, Dr. K. P. : Relative Antiquity of the Ubeidiya Hominid, 1268
Moloney Leukaemia Virus : Immunological Tolerance of Neonatally Infected Mice to the (E. Klein and G. Klein), 163–5
Molson, G. R., Mackey, J. A , Smart, J. V., and Turner, Dr. P. : Effect of Promethazine Hydrochloride on Hand-Eye Co-ordination, 516
Molybdenum · Field Responses of Cereals to (J. W Gartrell), 1050
Molyneux, Dr. L. : Important Feature of Time Modulation, 188
Monash University, Melbourne · Chair of Applied Mathematics, 1070
Moniliformis dubius (Acanthocephala) : Uptake of Small Particles by (Dr. S. J. Edmonds and B. R. Dixon), 99
Monkey (*Macaca mulatta*) to *H*-1 Virus : Susceptibility of the Rhesus (Prof. H. W. Toolan), 833
Monkey : Pacinian Corpuscle on the Olfactory Bulb of the Squirrel (Dr. T. R. Shantha Veerappa and Prof G. H Bourne), 1260
Monkeys (*Macaca mulatta*) : Cortical Lesions and Interhemispheric Communication in (C R. Butler), 59–61
Monkeys · Cytoplasmic Inclusions in Neurones of Cercopithecus (Dr. M. Malherbe), 832
Monolayers at Liquid Interfaces (Dr. D. A. Haydon and M. J. Jaycock), 565
Mono-molecular Films : Demonstration of Ion-exchange Phenomena in Phospholipid (E Rojas *et al.*), 886
Mononuclears : Probable *in vivo* Origin of Multi-nucleated Giant Cells from Circulating (Dr. T Gillman and L. J. Wright), 263–5
Mononuclears in Repair and Fibrosis : Autoradiographic Evidence suggesting *in vivo* Transformation of Some Blood (Dr. T. Gillman and L. J. Wright), 1086–90
Monosynaptic *H*-Reflexes in Man : Fraction of the Motoneurone Pool activated in the (Dr. H. Táborniková), 206
Montagu, Katharine : Resistance of Gastrointestinal Tissues to Digestion by Gastric Juice, 1206
Monte Carlo Model of a Fracture Process (Prof. C. C Harris), 1302
Moon from *Luna* 9 (Dr. G Fielder, L. Wilson and J. E. Guest), 851–3
Moon Probe *Luna* 9 : Observations of the Russian (Prof. J. G. Davies *et al.*), 848–50
Moonlight on Activity of Aquatic Insects Depressant Effect of (Prof. N. H. Anderson), 319
Moore, C A., *et al.* : Spread of Potato Virus Y curtailed by Oil, 1370
Moore, David : New Method for Isolating Tetrads of Agarics, 1157
Moore, David P., *et al.* · Selective Inhibition of Cation Absorption by Uranyl, 1318
Moore, Richard E. M. : Pattern Formation in Aggregations of Varied Size and Shapes as seen in Mosaics, 128
Moore, Dr. R. L., and Krishnamurti, Prof. T. N. : Atmospheric Clear Air Turbulence, 462–4
Moore, T. O. : Elementary General Topology, *review* by Prof. L. S. Goddard, 952
Moore, W., *et al.* : Differentiation of Nucleated Red Blood Cells during *in vivo* Culture of Mouse Spleen and Thymus Cell Suspensions, 320
Morazain, Louis, *et al.* : Pharmacology of Akinesia : Investigations on 3,4-Dimethoxyphenylethylamine, 719–21
Morecambe Bay Reservoir Scheme, 1071
Morenkova, S. A. : Incorporation of ^{35}S-methionine into Insulin, 917
Morgan, Dr. C. H., *et al.* : Structures of 5-Bromodeoxyuridine and 5-Bromouridine, 1230–2
Morowitz, Prof. Harold J., and Waterman, Prof. Talbot H (edited by) : Theoretical and Mathematical Biology, *review* by Dr. I. J. Good, 1164
Morphologic Encyclopedia of Palynology : Definitions and Illustrations of Spores and Pollen (Prof. G. O. W. Kremp), *review* by Dr. W. G. Chaloner, 651
Morphological Analysis by Digital Computer, 858

Morphological Changes in Germ-free Mice : Antigen-Induced (P. Caster *et al.*), 1202–4
Morris, Dr. Desmond : The Mammals : A Guide to the Living Species, *review* by Dr. R. McN. Alexander, 443
Morris, Dr D., Hebb, Dr. C., and Bull, G. : Inhibition of Choline Acetyltransferase by Excess Cysteine, 914
Morrison, Prof. James : Retirement from the Chair of Crop and Animal Husbandry in the Queen's University of Belfast, 350
Morsches, B, et *al.*. Enzymatic Determination in Serum of Lathyritic and Prednisone-treated Lathyritic Rats, 1130

Nuclear Reactor (Dr. A Salmon), *review* by V. S Crocker, 1061
Nuclear-reactor Operation in Space : An Effect of (Capt. D. G Carpenter, Major R E. Denfeld and Major K. H. Kronlund), 64
Nuclear Structure in Lymphoid Primordia (L T Chen and Prof. R. F. Ruth), 381–3
Nuclear Test : Observations on Debris from the First Chinese (G Persson), 1228
Nucleated Red Blood Cells during *in vivo* Culture of Mouse Spleen and Thymus Cell Suspensions : Differentiation of (Dr. S. Albert, P Wolf, I Pryjma and W. Moore), 320
Nucleic Acid : Attempts to induce Leukaemia by Incubation of Mouse Thymus Cells with Leukaemic Cell (Dr. E. F. Hays), 1327–30
Nucleic Acid Constituents (D. E. Homes et *al*), 1017
Nucleic Acids and Other Biological Polyanions : Binding of Cationic Dyes to (Dr. J. E Scott and Dr. I. H. Willett), 985–7
Nucleic Acids Infectivity of Gross and Rauscher Leukaemia Viruses and their (Dr E. F. Hays and P F. Alpert), 1326
Nucleic Acids of Malignant and Benign Splenic Hyperplasias in Mice (L. Kravetz de Srulijes, E A. D. Holmberg, A. Pavlovsky and S L. Rabasa), 1038
Nucleo-cytoplasmic Concentration Gradient of Chloride in Rat Liver · High (H Langendorf, Prof. G Siebert, K. Kesselring and R. Hannover), 1130
Nucleoproteins : Calf Thymus and Chicken Erythrocyte (M. Champagne and A Mazen), 1131
Comparative Immunochemical Properties of (Prof. R. H Wilson et *al.*), 1102–5
5′-Nucleotidase and Non-specific Alkaline Phosphatase Activities · Separation of Serum (Dr. D W. Moss), 806
Nucleotides and Purines at *p*H 7 0 and in 2 N Hydrochloric Acid : Ultra-violet Extinction Coefficients of some Muscle (P. W. Ratcliff and M. J. Follett), 1129
Nucleus to the Cytoplasm : Polysomes on a Nuclear Membrane Fraction as Intermediates in the Transfer of RNA from the (Dr M. K. Bach and H. G. Johnson), 893–5
Nucleus : Kinetics of Two-break Chromosome Exchanges and the Spatial Arrangement of Chromosome Strands in Interphase (Dr. Sushil Kumar and Dr. A. T Natarajan), 796
Nuclides rather than the Conventional Packing Fraction Superiority of Atomic Mass per Nucleon as a Parameter for (H. B. Klepp), 1344
Nuffield Foundation Report for the Year ended 31 March, 1965, 251
Number of Interacting Particles and Flux Ratio : Relationship between the (Dr. H G. Britton), 296
Numerical Methods in Subsonic Fluid Dynamics (P. G. Williams), 766–8
Nurseries : Forest (Dr. C. J. Taylor), 146
Nutrition and Caries-prevention (edited by G. Blix), Symposium, *review* by Prof. R. B. Lucas, 1275
Nutrition of Cotton as influenced by Sodium : Magnesium (M W. Thenabadu), 165
Nutritional Muscular Dystrophy in the Chick : Effect of Kidney Beans (*Phaseolus vulgaris*) on Plasma Tocopherol-level and its Relation to (Dr. I. D. Desai), 810
Nutritional Requirements : Canine and Feline (edited by O Graham-Jones), *review* by P. R Payne, 847

Oakley, Dr Kenneth P., and Molleson, T. I. : Relative Antiquity of the Ubeidiya Hominid, 1268
OB Associations and Cosmic X-ray Sources : Supernova Phenomena in (L. L. E. Braes and J. W. Hovenier), 360
Oceanography . National Institute of (Mrs. M. Swallow), 142–5
Advances in, 562
Anglo-French Co-operation in, 1288
Oceans : Physical Geography of the (C. H. Cotter), *review* by Prof. K F. Bowden, 649
Ockey, Dr. C. H , et *al* : Synchrony of Chromosome Duplication, 537
O'Connor, Maeve, and Wolstenholme, Dr. G. (edited by) : Man and Africa, *review* by Dr. A. S. Thomas, 548
O'Connor, Maeve, and Wolstenholme, G. E. W. (edited by) : Caries-resistant Teeth, *review* by Prof R. B. Lucas, 1275
Octopus · Intraretinal Discrimination of Horizontal and Vertical Planes of Polarized Light by (Prof. K. Tasaki and Prof. K. Karita), 934
Odell, Prof A. L., et *al.* : Catalysis by Alkali Metal Ions of the Racemization of the *Tris*-oxalato Chromium III Anion, 906
Odell, Prof. A. L., Packer, Dr. J. E., and White, G. R. : Labelled Products from the Internal Radiolysis of Liquid *Cyclo*hexane saturated with Tritium Gas, 72

Odell, Carl A., and Gale, Dr. G. R. : Antagonism of Colistin-sulphonamide Synergism by *para*-aminobenzoic Acid, 1357
O'Dell, B. L., Elsden, D. F. Thomas, Dr J , Partridge, Dr. S. M., Smith, R. H., and Palmer, R. : Inhibition of the Biosynthesis of the Cross-links in Elastin by a Lathyrogen, 401
Odom, J , *et al.* : Naturally Occurring Foetal Haemoglobin Hybrid, 721
Odour and Molecular Vibration (R H. Wright), 571–3
Odour? : Why is an (R. H. Wright), 551–4
Oestradiol in Adrenal Corticoidogenesis : an Additional Step in Steroid Biosynthesis . Effect of (Prof. J. I Kitay), 808
Oestradiol · Brain Myelination after Neonatal Administration of (J. J. Curry, III and Prof. L. M. Heim), 915
Oestrous Cycle in the Rat Behavioural Correlates of the (A. W. Burke and Prof. P. L Broadhurst), 223
Offspring : Tranquillizers in Pregnancy and Behavioural Effects on the (Dr. J. Werboff), 110
Ogden, C P , *et al.* : Extinction Coefficient of Water at 2 93μ and Water Content of Black Foam Films, 1192
Ogilvie, Dr. Bridget M , Smithers, Dr S. R., and Terry, Dr. R. J. : Reagin-like Antibodies in Experimental Infections of *Schistosoma mansoni* and the Passive Transfer of Resistance, 1221–3
OH Emission Sources near W3 and W49 . Detection of Circular and Linear Polarization in the (Dr. R. D. Davies *et al.*), 974–7
Ohnuki, Dr. Yasushi, *et al.* . Effect of Sodium Fluoroacetate on Myocardial Cells *in vitro*, 1197
Oil and Gas Pipelines in Europe, 1288
Oil : Spread of Potato Virus y curtailed by (R. H E Bradley *et al.*), 1370
O'Keefe, Dr. J. A., and Lowman, jun., Dr. P. D. Terrestrial Origin of the Igast Objects, 67
Okigaki, Dr. Tohru, *et al.* : Effect of Sodium Fluoroacetate on Myocardial Cells *in vitro*, 1197
Old Age : Motor Unit in (E. Gutmann and V. Hanzlíková), 921
Olefines : Formation of Mercuric Iodo-acetate in Glacial Acetic Acid and its Reactions with (T. D. Smith), 907
'O'-Level Examinations, 460
Olfactory Bulb of the Squirrel Monkey Pacinian Corpuscle on the (Dr T. R Shantha veerappa and Prof G. H. Bourne), 1260
Oligoadenylic Acids and a Consideration of the Factors Stabilizing Helical Polynucleotides Optical Rotatory Dispersion of (Dr. A. M. Michelson *et al.*), 873
Oligomycin Inhibition of Ion Transport in Plant Roots (Prof T. K. Hodges) 425
Oliva, Luis, *et al.* : Pharmacology of Akinesia : Investigations on 3, 4-Dimethoxyphenylethylamine, 719
Olive Fly . *Dacus oleae*, Larvae on Symbiosis with *Pseudomonas savastanoi* for the Utilization of Olive . Dependence of the (Dr. K. S Hagen), 423
Oliver, Dr. D. S. : Phase Equilibria among Oxides in Steelmaking, *review*, 845
Oliver, R. : British Radiological Protection Association and the Joint Health Physics Committee, 862
Olliff, R. W., *et al.* : Catalysis by Alkali Metal Ions of the Racemization of the *Tris*-oxalato Chromium III Anion, 906
Olovnikov, A. M., and Gurvich, A E : Immunization with Protein-Cellulose Copolymer (Immunosorbent), 417
Olthof, Th. H. A., and Estey, Prof. R. H Carbon- and Nitrogen-levels of a Medium in Relation to Growth and Nematophagous Activity of *Arthrobotrys oligospora* Fresenius, 1158
Oncogenic Viruses : Collagen Synthesis in Fibroblasts transformed by (Prof. H. Green *et al*), 916
Oncogenicity in Hamsters by Simultaneous Inoculation with Adenovirus 5 : Inhibition of Adenovirus 12 (J Peries *et al.*), 738
Onoda, Tetsuo, *et al.* : Metabolism of *Spirogyra* during the Conjugation Process, 1042
Onychophora : Composition of the Blood in (Dr. E. A. Robson *et al.*), 533
Oozes from the Mid-Atlantic Ridge : Cemented Foraminiferal (Dr. R. Cifelli *et al*), 32–4
Opal : Origin of Precious (P. J Darragh *et al*), 13–16
Operon of *Escherichia coli* . Isolation of the Permease Expression of the *LAC* (Dr. A. R Kolber and Dr. W. D Stein), 691–4
Operon Hypothesis New Evidence from the 'Constant Proportion' Group of the Embden-Meyerhof Pathway (Dr. P. D. Mier and D. W K Cotton), 1022
Optical Asymmetry : Quasars, Antimatter and (Dr T L V Ulbricht), 391
Optical Illusions (Dr. G. K. Wallace), 327; (Dr. R. L. Gregory), 327
Optical Radar : Backscattering from the Upper Atmosphere (75–160Km) detected by (P. D McCormick *et al.*), 798
Optical Rotatory Dispersion of Oligoadenylic Acids and a Consideration of the Factors Stabilizing Helical Polynucleotides (Dr. A. M Michelson, Dr. T. L. V. Ulbricht, Dr T. R. Emerson and R. J Swan), 873
Optically Active Petroleum Distillates · Triterpanes in (I R. Hills and E. V. Whitehead), 977–9
Ordinary-level Examinations, 460
Ordy, Dr. J Mark, *et al* : Psilocin : Effects on Behaviour and Brain Serotonin in Mice, 785–7
Orfila, Dr J , *et al* : Fluorescent Antibodies in the Fluid of the Conjunctival Sac of Trachoma Patients, 725
Organic Carbon and to Palaeosalinity in Certain British Upper Carboniferous Sediments . Boron Content in Relation to (Dr. R. M C. Eagar and Dr D A Spears), 177–81
Organic Molecules : Reactivity of Photo-excited (Prof A R Ubbelohde), 28
Organisms · The Biology of (Prof W. H Telfer and Prof D. Kennedy), *review* by B. B. Boycott and Dr. A. Curtis, 1276
Organization for Economic Co-operation and Development, 760
Organization of Research Establishments (edited by Sir John Cockcroft), *review* by Dr. C. P. Haskins, 946–8
Organization of the Scientific Civil Service, 968
Orifice · Hysteresis in the Flow through an (B. E L. Deckker), 604
Origin of the Igast Objects : Terrestrial (Dr P. D. Lowman, jun., and Dr. J A. O'Keefe), 67
Origin of Multi-nucleated Giant Cells from Circulating Mononuclears : Probable *in vivo* (Dr. T. Gillman and L. J Wright), 263
Origin of Some Naturally Occurring Hydrocarbons : Possible Abiogenic (Dr. C Ponnamperuma and K. Pering), 979–82
Origin of Precious Opal (P. J. Darragh *et al.*), 13–16
Orkand, Dr. Paula, and Miledi, Prof R. : Effect of a 'Fast' Nerve on 'Slow' Muscle Fibres in the Frog, 717
Ørskov, Dr. Fritz, *et al.* : K88, an Episome-determined Protein Antigen of *Escherichia coli*, 507
Ørskov, Dr. Ida, *et al.* : K88, an Episome-determined Protein Antigen of *Escherichia coli*, 507
Orth, Charles D., Bailey, Prof. J. C., and Wolek, F W. · Administering Research and Development, *review* by W. Jackson, 1061
o-Phenylenediamine Cleavage of Ketones Mechanism of the (Dr. G. E. Risinger), 1022
Osato, T., Mirand, Prof. E A., Grace, jun , J. T , and Price, F. : *In vitro* Malignant Transformation of Cells by Friend Virus, 779–82
Osborn, Prof. E. F , and Muan, Prof. A. : Phase Equilibria among Oxides in Steelmaking, *review* by Dr. D S Oliver, 845
Oscillation in Enzyme Reactions (Prof. C. Walter), 404
Oscillations in Electrical Potential at Probe Electrodes in Membrane Transport Cells : Anharmonic (Prof. J W. Lorimer *et al.*), 1019
Oscillations in a Peroxidase-like Enzyme Reaction : Highly Damped (Prof. E. H. Strickland and Prof E. Ackerman), 405
Osmolality of Hypophysectomized Killifish, *Fundulus heteroclitus*, in Freshwater : Prolactin and Serum (Prof. G. E. Pickford *et al.*), 1040
Oudea, P., *et al.* : Presence in Colic Glandular Cells of Various Mammalian Species of an Antigen Cross-reacting with Human Blood Group A Substance, 159–61
Overcrowding in Schools, 136
Over-dominance during the Initial Spread of New Alleles . Evolution of (S. K. Jain), 429
Overmeer, W. P. J. Intersterility as a Consequence of Insecticide Selections in *Tetranychus urticae* Koch (Acari · Tetranychidae), 321
Overseas Aid in its Proper Perspective, 437
Overseas : British Government Aid, 965, 966
British Teachers, 1177
Ovum : Synthesis of a Ribonucleic Acid Virus by the Mammalian (R. B. L Gwatkin and S. Auerbach), 993
Owens, jun., Dr. Albert H , and Santos, Prof G. W. : 19S and 7S Antibody Production in the *Cyclo*phosphamide- or Methotrexate-treated Rat, 622
Ox : Development of *Boophilus decoloratus* (Koch, 1844) on the (V. Ammah-Attoh), 629
Oxidation of Cyclic Ketones : Microbiological (Dr R Shaw), 1369
Oxidation of *Cyclo*hexane by Lead Tetra-acetate (J Ujhazy and Prof. E. R. Cole). 395
Oxidation-reduction State : Ionizing Radiation and the Intracellular (D. Jamieson), 361–5
Oxide Films on Aluminium and its Alloys : A C Resistivity Profiles through Anodic (Dr. G. C. Wood and Dr. A J. Brock), 773–5
Oxides in Steelmaking Phase Equilibria among (Prof A. Muan and Prof. E. F. Osborn), *review* by Dr D. S. Oliver, 845
Oxygen Consumption of Slices from Kidney, Brain, Cortex and Liver in Hypoxia : *In vitro* (J Skolnik, Dr A. Takacs and E Szende), 305
Oxygen Demand Rates and Oxygen Utilization Rates . Comparison of (Prof. Robert M. Arthur), 104
Oxygen Isotopes by Gas Chromatography : Separation of (W. Bocola *et al*), 200
Oxygen : Kinetics of the Reaction of Nitric Oxide with Molecular (Dr M. Solc), 706
Oxygen using Molecular Sieve . Chromatographic Separation of Argon and (J A. J Walker), 197
Oxygen and Phytoplankton Changes in the newly forming Volta Lake in Ghana (Dr S. Biswas), 218
Oxygen : Regulation of Cellular Autolysis by Hyperbaric (Dr. R. M. Rosenbaum *et al*), 895
Oxygen Transfer by Carotenoids in Respiration and Photosynthesis Further Proof of Direct (Dr. E. Haspel-Horvatović), 1135
Oxygenation . Hyperbaric (edited by I. McA. Ledingham), *review* by Prof. R. E. Coupland, 949
Ozone in the Stratosphere : Correlation of Dust and (Dr J. M. Rosen), 1342

P_1 Blood Group Substance in *Lumbricus terrestris* (Earthworm) and *Ascaris suum* (Prof O. Prokop and D. Schlesinger)), 1255
Pacific Ocean : Cloud Structure and Distributions over the Tropical (J S. Malkus and H. Riehl), *review* by P. Graystone, 234
Pacific, 1962 . Radionuclides in Foods from the Central ([The late] Prof. R. F. Palumbo *et al*), 1190–2
Pacini, Dr. Franco : High-energy Astrophysics and a Possible Sub-nuclear Energy Source, 389
Pacinian Corpuscle on the Olfactory Bulb of the Squirrel Monkey (Dr. T. R. Shantha Veerappa and Prof. G. H Bourne), 1260
Packer, Dr J E., *et al* : Labelled Products from the Internal Radiolysis of Liquid *Cyclo*hexane saturated with Tritium Gas, 72
Packing Fraction : Superiority of Atomic Mass per Nucleon as a Parameter for Nuclides rather than the Conventional (H. B Klepp), 1344
Palaeocurrents in the Upper Cambrian of North Wales (Dr. A. M. Evans, P Garrett and J. H McD. Whitaker), 1230

Prolactin and Somatotrophin in Organ Culture : Strain Differences in Mouse Mammary Tissue Sensitivity to (E. M Rivera), 1151
Prolactins and Pituitary Growth Hormones estimated by Gel Filtration : Molecular Weights of (Dr P Andrews), 155–7
Prolongation of Life or Survival of Lactating Mice in Infections with *Trypanosoma cruzi* : Retardation of Parasitaemia, (Dr H E Krampitz and R. Disko), 526
Promethazine Hydrochloride on Hand-Eye Co-ordination Effect of (G. R. Molson, J A. Mackey, J. V Smart and Dr. P Turner), 516
Propiolactone on Rat Fibrocytes : Effects of a (Dr. A. K Powell), 77
Propranolol on the Peripheral Vascular Bed : Effect of (Prof. J Nakano and T Kusakari), 923
Prostaglandin E_1 on Brain-stem Neurones : Excitatory Action of (Dr. G. L. Avanzino *et al.*), 87
Prostaglandins, Antagonism by, of the Responses of Various Smooth Muscle Preparations to Sympathomimetics (Dr. P C Clegg), 1137–9
Protandrous Hermaphroditism in Decapod Prawns of the Families Hippolytidae and Campylonotidae (Y C. Yaldwyn), 1366
Protection against Ionizing Radiation . Chemical (Prof Z. M. Bacq), *review* by J. H. Barnes, 547
Protein? : Is the Antihaemophilic Globulin a (H. A. Veder), 202
Protein Biosynthesis in Hepatoma 223 · Rate of (Dr. J. N Mansbridge and Dr A. Korner), 402
Protein-Cellulose Copolymer (Immunosorbent) . Immunization with (A. M. Olovnikov and A E. Gurvich), 417
Protein : Colour, Magnetic Resonance and Symmetry of the Cupric Site in Blue (H. J. Maria), 1023
Protein in Liver Tissue of the Rat · Sex-associated (Dr. H E. Bond), 1026
Protein Synthesis with Age in *Drosophila subobscura* : Increase in the Rate of (J. M. Clarke and Prof. J Maynard Smith), 627
Protein Synthesis of Frog Embryo Cells by Larval and Adult Frog Liver Ribonucleic Acid Preparations : Stimulation of (E. Rollins, M. Miyagi, C R. Moser and Prof. R. A. Flickinger), 509
Proteins Evolving Genes and (edited by V Bryson and H. J Vogel), *review* by Dr B. F. C Clark, 747
New Chromophoric Reagents for Labelling the Thiol Groups of, 457
Variations in Amino-acid Sequence near the Disulphide Bridges of Bence-Jones (Dr. C Milstein), 370–3
Proteins on the Adhesiveness of Red Cells : Effect of Basic (Dr. E. Ponder), 307
Proteins of Wheat Leaf : Electrophoresis of the Soluble (C. W. Wrigley *et al*), 1133
Proteolytic Enzymes of *Citellus citellus* and *Spalax leucodon* (M. I. Janković, J. S. Grozdanović and I. R Savić), 316
Proteolytic Enzymes in Normal and Leukaemic Human Leucocytes : Distribution Patterns of (Prof. R. J Haschen and Dr. K. Krug), 511
Proteus mirabilis · Linked Transduction in (Dr. O. W. Prozesky and Prof J. N. Coetzee), 1262
Prototheca zopfii . Adaptive Butyrase Enzyme System in the Alga (Dr. D. R. Cullimore), 531
Prothero, Dr R. Mansell Migrants and Malaria, *review* by Prof. G. Macdonald, 337
Prothrombin · Prethrombin as a New Sub-unit of (Dr. E Marcinak and Prof. W. H Seegers), 621
Protochordata, 1073
Proton Transfer Processes in Muscle : Pressure, Temperature and Isotopic Effects, (Dr. R A. Horne and D. S. Johnson), 82
'Protoplasts' from Fungal Mycelium : Use of Lipase and Strepzyme for the Isolation of (I. G. Acha *et al.*), 95
Protoporphyrin Metabolism in Leukaemic Cells · Hypothetical Significance of Disturbances of Zinc and (Dr S Szmigielski), 411
Protozoa · An Alternative Multi-target Equation useful for fitting Survival Curves of X-ray Irradiated (Dr. J. Calkins), 172
Protozoan Parasite of *Molgula manhattensis* (De Kay) (Urochordata) (C. H Burren), 101
Prozesky, Dr O W., and Coetzee, Prof. J. N Linked Transduction in *Proteus mirabilis*, 1262
Pryjma, I., et *al* Differentiation of Nucleated Red Blood Cells during *in vivo* Culture of Mouse Spleen and Thymus Cell Suspensions, 320
Pseudomonas savastanoi for the Utilization of Olive : Dependence of the Olive Fly, *Dacus oleae*, Larvae on Symbiosis with (Dr. K S Hagen), 423
Psilocin Effects on Behaviour and Brain Serotonin in Mice (Dr. R. L. Collins, Dr. J. M. Ordy and Dr. T. Samorajski), 785–7
'Psilocybin' . Time Contraction and Psychomotor Performance produced by (Prof R. Fischer and E L. Mead), 433
Psychiatry Modern Perspectives in Child (edited by Dr. J. G. Howells), *review* by Prof O. L. Zangwill, 120

Psychoactive Agent · Pharmacological Investigation of a New (Prof. B. Korol et al), 1249
Psycho-Analytic Dialogue · Letters of Sigmund Freud and Karl Abraham, 1907–1926 (edited by H. C. Abraham and E. L. Freud), *review* by Dr. C. Allen, 1274
Psychomotor Performance produced by 'Psilocybin' : Time Contraction and (Prof. R. Fischer and E. L. Mead), 433
Puccinia coronata Field Resistance in *Lolium* sp. to Leaf Rust (Dr J G Gibbs), 420
Puccinia graminis avenae induced by Ethyl Methane Sulphonate : Mutants of (Dr. E. P Baker and C. Teo), 632
Pugh, L G C. · Clothing Insulation and Accidental Hypothermia in Youth, 1281–6
Pulses across the Interface between Two Immiscible Liquids . Propagation of Stress (Dr D. H. Trevena), 289
Pumice from the South Sandwich Eruption of March 1962 reaches New Zealand (Prof. D. S. Coombs and C. A Landis), 289
Puppi, A., et *al*. Various Cell Types in the Adrenal Medulla, 592–4
Pure Chemicals Developments in, 858
Purification and Lability of Human Follicle-stimulating Hormone (Dr S. M. Amir, Dr. S. A Barker, Dr. W. R. Butt and Dr. A C Crooke), 1092
Purines at pH 7 0 and in 2N Hydrochloric Acid Ultra-violet Extinction Coefficients of Some Muscle Nucleotides and (P. W Ratcliff and M J. Follett), 1129
Pyelonephritis in the Rhesus Monkey : Experimental (S. K. Datta and Prof. R. N Chakravarti), 90
Pyrimidine Nucleotides in Deoxyribonucleic Acids · Use of Acidic Degradation for the Determination of the Distribution of (Dr. A. S. Jones et *al.*), 296
Pyrocarbonic Acid on Bacteriophage and Transforming DNA : Effects of the Diethyl Ester of (I Fedorcsák and I. Turtóczky), 830
Pyruvate in Urea-denaturation of Lactic Dehydrogenase Isozymes : Reduced Nicotinamide-adenine Dinucleotide and (S Lindy and Dr. Z. Konttinen), 79
Pyruvate Kinase in Normal Individuals and in a Patient with Pyruvate Kinase Deficiency . Investigations of the Kinetics of Red Cell (Dr. U. Wiesmann and Dr. O. Tonz), 612
Pyruvate in Muscle : Glycogen Synthesis from (Dr. R. Mahler), 616
Pythium debaryanum to Structures recently described in *Chara* and *Nitella* : Resemblance of Lomasomes of (R. J Hendy), 1258
Pythium graminicola : Factors controlling Sexual Reproduction and Growth in (Dr. J. F. Lenney and Dr. H. W. Klemmer), 1365

Quantitation of Peripheral Blood Lymphocyte Cultures (A. S. Coulson and Dr. D. G. Chalmers), 378–81
Quantock, Dr. D C., et *al* . Stimulation of Phagocytosis in Relation to the Mechanism of Action of Adjuvants, 1142
Quantum Efficiency in Rhodopsin Bleaching : Limitations on the Use of the Concept of (Prof T. P. Williams), 1350
Quantum Electrodynamics (A I. Akhiezer and V. B. Berestetskii), Second Edition, *review* by Prof P. M Davidson, 121
Quantum Yield of 1-Dimethylaminonaphthalene-5-sulphonate · Fluorescence (Dr. R. F. Chen), 69
Quasars, Anti-matter and Optical Asymmetry (Dr T. L. V. Ulbricht), 391
Quasars : Lightning, Novae and (Dr. C. E R Bruce), 798
Quasi-stellar Sources On the Nature of the (Prof. F. Hoyle, Prof G R Burbidge and Prof. W. L W Sargent), 751–3
Quastel, Prof. J. H. : Sixty-fifth Birthday Tribute in *Canadian Journal of Biochemistry*, July, 1965, 350

University of Sussex : Appointments in Theoretical Astronomy, 19
First Professor of Mechanical Engineering, 965
Appointments, 860
University of Swansea : Chair of Genetics, 249
Unnewehr, F., *et al.* : Distribution of Caesium-137 in the Human Organism and in the Human Foetus, 1310–2
Untrained Rats by means of a Brain Extract : Transfer of Conditioned Responses from Trained Rats to (Dr F. Rosenblatt et *al.*), 46
Unweaned Rats : Method of Isolating and Counting *Nippostrongylus brasiliensis* from (P. Whur and M. Gracie), 630
Upper Atmosphere (75–160 Km) detected by Optical Radar : Backscattering from the (P. D. McCormick et *al*), 798
Upper Cambrian of North Wales : Palaeocurrents in the (Dr. A. M. Evans et *al.*), 1230
Upper Carboniferous Sediments : Boron Content in Relation to Organic Carbon and to Palaeosalinity in Certain British (Dr. R. M. C. Eagar and Dr. D. A. Spears), 177
Upper *F* Region : Night-time Electron Temperatures in the (K. V. S. K. Nathan and Prof. M. J Seaton), 701
Upshall, Alan : Somatically Unstable Mutants of *Aspergillus nidulans*, 1113–5
Uptake of Amino-acid and Incorporation in Isolated Rabbit Diaphragm : Effect of Vitamin E Deficiency on (Prof. J. F. Diehl), 75
Uptake of Iodine-131 and Circulating Iodine Compounds : Influence of Cold on Thyroid (Dr. J. P Salvanesch: et *al*), 1240
Uptake of Plutonium by the Lobster *Homarus vulgaris* (E. E. Ward), 625
Uptake of Small Particles by *Moniliformis dubius* (Acanthocephala) (Dr. S. J. Edmonds and B R Dixon), 99
a-Uranium : Enhancement of Ductility in (Dr. R H. Johnson and E. C. Sykes), 192
Uranium . Manufacture of Enriched, 250
Uranyl · Selective Inhibition of Cation Absorption by (B. J. Mason et *al*), 318
Urban Traffic Problems, 1297
Urea-denaturation of Lactic Dehydrogenase Isozymes : Reduced Nicotinamide-adenine Dinucleotide and Pyruvate in (S. Lindy and Dr. A. Konttinen), 79
Urease in the Rumen Wall and Rumen Content : Comparative Study of the (Dr. S. Abdel Rahman and Prof. P Decker), 618
'Urethan' *in vitro* . Chemical Deletion of Histocompatibility Antigens—Homograft Survival of Rat Skin treated with (E Bonmassar et *al.*), 1141
Urinary Excretion of Acetylsalicylic Acid in Man (A. J. Cummings and M. L. King), 620
Urinary Isoamylases on Cellulose Acetate : Separation of (Dr S E. Aw), 298
Urinary Methylated Purines : Origin of (Dr. L. R. Mandel, Prof. P. R Srinivasan and Prof. E. Borek), 586–8
Urobilins : Molecular Species of the (Dr. A. H. Jackson, K. M. Smith, Prof. C. H. Gray and Dr. D. C Nicholson), 581–3
(Urochordata) : A Protozoan Parasite of *Molgula manhattensis* (De Kay) (C.H. Burren), 101
Usefulness of Materials : Extending the (Dr. W. A. Homes-Walker), 1292–6
Uterine Growth of Hypophysectomized Mice : Effect of Gonadotrophins on (Dr. D R. Lamond and B. M. Bindon), 512
Uterus of Hens during Moult : Behaviour of Carbonic Anhydrase in the (J. Schlüns and T. Diamantstein), 304
Utopiates : Use and Users of LSD 25 (Dr. R. Blum et *al.*), *review* by Dr. J. R. Smythies, 441

Vaccinia Virus *in vitro* : Effect of 'Cephaloridine' on (Dr. M. Nishnii), 222
Vacuum using an Ionization Gauge : Measuring the Density and Direction of Molecular Flow in High (L Holland and C Priestland), 274
Valzey, M Jane, and Hutt, C : Differential Effects of Group Density on Social Behaviour, 1371
Values in an Age of Technology : Educational (F. B Pinion), *review* by R. Brightman, 844
Values : Education and (G. H. Bantock), *review* by R. Brightman, 844
Vanadium and Dental Caries (Prof. D. M. Hadjimarkos), 1137
Van Andel, Dr. Tjeend H., *et al.* : Greenstones from the Central Valley of the Mid-Atlantic Ridge, 604
Vand, Prof. V. : Munro Jets and the Origin of Tektites, 496
Vandenberk, J., *et al* · Tetramisole (*R* 8299), A New, Potent Broad Spectrum Anthelmintic, 1084–6
Van Londen, Dr. A. M., and de Wolf, Dr. P. : Anti-fouling Compositions, 272–4

Vanparijs, O. F. J., *et al.* : Tetramisole (*R* 8299), A New, Potent Broad Spectrum Anthelmintic, 1084–6
Van Wijk, U., *et al.* : Backscattering from the Upper Atmosphere (75–160 Km) detected by Optical Radar, 798
Vapour Phase in Terrestrial and Lunar Volcanism : Evaporation of Lava and its Condensation from the (Dr. B. Vonnegut *et al.*), 445–8
Variation in the Spontaneous Ejaculations of the Male Albino Rat : Diurnal (Prof. J. E. Kihlstrom), 513
Variations induced with a Magnetic Probe : Cytogenetic (W. C. Levengood), 1009–13
Vascular Bed : Effect of Propranolol on the Peripheral (Prof. J. Nakano and T. Kusakari), 923
Vascular Tissue : α-Hydroxybutyric Dehydrogenase Activity of Human (R. Sanwald and Prof J. E. Kirk), 912
Vassiljeva, N. N., *et al.* : Small-plaque and Large-plaque Variants of Papova Virus SV_{40}, 1048
Vasudev, A., and Heideger, Prof. W. J. : Equilibrium at the Solid-Liquid Interface, 295
Vector : Effects and After-effects on Planarians of Reversals of the Horizontal Magnetic (Prof. F. A. Brown, jun.), 533
Veder, H. A : Is the Antihaemophilic Globulin a Protein? 202
Vegetation Types, 859
Vella, Dr. F., Beale, Dr. D, and Lehmann, Dr. H : Haemoglobin O Arab in Sudanese, 308
Velocities : Dislocation (Prof. P P. Gillis), 1119
Velocity Coefficients in the Polymerization of Methyl Methacrylate : Effect of Zinc Chloride on the (Prof. C. H. Bamford *et al.*), 292
Veneroni, E., *et al.* : Triglyceride Accumulation in Liver, 1025
Venom of the *Megalopyge urens* (Berg) Caterpillar (Dr. M. I. Ardao, C. Sosa Perdomo and M. G. Pellaton), 1139
Venting of a Soviet Underground Nuclear Test : Highly Fractionated Nuclear Debris resulting from the (Prof. S Koyama *et al.*), 239
Ventricular Compliance : Variable Diastolic (Dr. B. J. Scherlag *et al.*), 1246–8
Venus? : Resonant Rotation for (P. Goldreich and S J. Peale), 1117
Verdura, Dr. Javier, *et al.* : Prolonged Whole-brain Refrigeration with Electrical and Metabolic Recovery, 1320–2
Vergani, Carlo, *et al.* : Intracellular Distribution of the Different Forms of Lactic Dehydrogenase, 1024
Vernon, Dr. Jack A : Inside the Black Room, *review* by Dr. E. J. Dingwall, 748
Vernon-Roberts, Dr. B., *et al* Stimulation of Phagocytosis in Relation to the Mechanism of Action of Adjuvants, 1142
Verschuur, Dr. G. L, *et al.* : Detection of Circular and Linear Polarization in the OH Emission Sources near W3 and W49, 974–7
Vertebrate Epidermal Melanin Unit (M. E Hadley and W. C. Quevedo, jun), 1334
Vestri, R., Felicetti, L., and Lostia, O. : Transformation by Hybrid DNA in *Bacillus subtilis*, 1154
Veyre, C., *et al.* : Presence in Colic Glandular Cells of Various Mammalian Species of an Antigen Cross-reacting with Human Blood Group A Substance, 159–61
Vibration : Odour and Molecular (R. H. Wright), 571–3
Vibration : Reflex Activation of the Soleus Muscle of the Decerebrate Cat by (Dr. P B. C Matthews), 204
Vibrational Energy into Rotational Energy in the Nitrogen Molecule : Change of (Dr. C. B Sharma), 1226
Vick, L. L. J. : Collected Papers of L. D. Landau, *review*, 847
Vidaud, P. H , and von Engle, Dr. A. : Electric Breakdown in Non-virgin Gases, 1345
Vietz, J. T., *et al.* . *T*-phase Precipitation induced by the Addition of Silver to an Aluminium-Copper-Magnesium Alloy, 703
Vijayalakshmi, B , *et al.* : Energy Spectrum of Primary Cosmic-rays, 567–9
Villa, Luigi, *et al* . Intracellular Distribution of the Different Forms of Lactic Dehydrogenase, 1024
Villanueva, Dr. J. R , *et al.* : Use of Lipase and Strepzyme for the Isolation of 'Protoplasts' from Fungal Mycelium, 95
Viral Leukaemogenesis : Influence of Thymic Mass on Murine (Dr. R. Siegler and Dr M. A Rich), 313
Virial Coefficient : Partition Isotherms and the Mixed Second (Dr. G. F. Freeguard), 1124
Virus : Immunological Tolerance of Neonatally Infected Mice to the Moloney Leukaemia (E. Klein and G. Klein), 163
Isolation of a Tumour Virus from a Chicken submitted to a Poultry Diagnostic Laboratory–Esh Sarcoma (Prof. A M. Wallbank *et al.*), 1265
In vitro Malignant Transformation of Cells by Friend (T. Osato *et al.*), 779–82
Susceptibility of the Rhesus Monkey (*Macaca mulatta*) to *H*-1 (Prof. H. W. Toolan), 833
Virus from the Brain of Fowl : a Cytopathogenic (F. B Halpin), 429
Virus *in vitro* : Effect of 'Cephaloridine' on Vaccinia (Dr. M. Nishmi), 222
Virus Disease in Crustacea, 1290
Virus Disease : Passive and Active Immunity to Friend (Prof. E. A. Mirand *et al.*), 696–8
Virus by the Mammalian Ovum : Synthesis of a Ribonucleic Acid (R. B. L. Gwatkin and S. Auerbach), 993
Virus Name? What's in a (Dr A J. Gibbs, Dr. B. D. Harrison, Dr. D. H. Watson and Prof. P. Wildy), 450–4
Virus Particle Size and Activity of Antiviral Agents : Possible Correlation between (Dr. D J. Bauer), 639
Virus Ribonucleic Acid : Investigation of Rauscher (F. Galibert *et al*), 680–2
Virus SV_{40} Small-plaque and Large-plaque Variants of Papova (Dr. A. D. Altstein *et al.*), 1048
Virus on Tumour-bearing Mice : Action of Riley's Enzyme-elevating (Dr. A. Georgii *et al.*), 929
Virus Y Curtailed by Oil : Spread of Potato (R. H. E. Bradley *et al*), 1370
Viruses : Collagen Synthesis in Fibroblasts transformed by Oncogenic (Prof. H. Green *et al.*), 916
Viruses and their Nucleic Acids : Infectivity of Gross and Rauscher Leukaemia (Dr. E F. Hays and P. F. Alpert), 1326
Visual Anomaly : Evoked Potentials Correlated with a (Prof. D. M. Mackay and Dr A. Fiorentini), 787–9
Visual Classification Transmission of Indian Mica between 300 and 1,000 mμ and its (R. N. Dhar and S. R. Das), 185
Visualization of Low-speed Flow using Suspended Plastic Particles (Dr. S. Vogel and Prof. N Feder), 186
Viswamitra, Dr. M. A , and Kannan, K. K. : Molecular Dimensions and Crystal Structure of Dimethyl Sulphoxide at −60°C, 1016
Vita-Finzi, Dr C. : Historical Marine Levels in Italy, 906
Vitamin Assay : Tested Methods (R. Strohecker and H. M. Henning), *review* by Dr. F. W. Norris, 232
Vitamin E Deficiency on Uptake of Amino-acid and Incorporation in Isolated Rabbit Diaphragm : Effect of (Prof. J. F Diehl), 75
Vitis vinifera L. : Test-plants for Investigations of the Physiology of Fruiting in (Dr. M. G Mullins), 419
Vizoso, Dr. Alberto, D , Hay, R., and Battersby, T. : Isolation of Unidentified Agents capable of morphologically transforming Hamster Cells *in vitro*, 1263
Vogel, Henry J., and Bryson, V. (edited by) : Evolving Genes and Proteins, Symposium, 1964, *review* by Dr. B. F. C. Clark, 747
Vogel, Dr. Steven, and Feder, Prof. N. : Visualization of Low-speed Flow using Suspended Plastic Particles, 186
Volcanic Cauldrons, Ring Complexes and Associated Granites of the Georgetown Inlier, Queensland : Structure and Evolution of the (Dr. C. D. Branch), 606
Volcanic Chronology of Lanzarote (Canary Islands) (K. J. Tinkler), 1122
Volcanic Rocks from the Galapagos Islands : Palaeomagnetism and Potassium-Argon Ages of Some (Dr. A. Cox and Dr. G B. Dalrymple), 776
Volcanism : Evaporation of Lava and its Condensation from the Vapour Phase in Terrestrial and Lunar (Dr B. Vonnegut *et al.*), 445–8
Volcanology Research in New Zealand (Dr. I. G Gass and Dr. G. P. L. Walker), 1077
Volkenstein, Prof. M. V., Sharonov, J A., and Shemelin, A. K. : Anomalous Dispersion of the Faraday Effect in Haemoglobin and Myoglobin, 709
Vol'pin, Dr M. E , and Shur, V. B. : Nitrogen Fixation by Transition Metal Complexes, 1236
Volta Lake in Ghana : Oxygen and Phytoplankton Changes in the Newly Forming (Dr. S. Biswas), 218
Von Engel, Dr. A., and Vidaud, P. H. : Electric Breakdown in Non-virgin Gases, 1345
Vonnegut, Dr. Bernard, McConnell, jun., R. K., and Allen, R. V. : Evaporation of Lava and its Condensation from the Vapour Phase in Terrestrial and Lunar Volcanism, 445–8

W 3 and W49 : Detection of Circular and Linear Polarization in the OH Emission Sources near (Dr. R. D. Davies *et al*), 974–7
Wain, Prof. R. L., Balayannis, P. G , Taylor, H. F., and Zaki, M. A. : Selective Herbicidal Activity of oxides, 98
Wales : Caledonian Magmatism in North (J. E. Thomas *et al.*), 866–8
National Museum of, 1071
Palaeocurrents in the Upper Cambrian of North (Dr. A. M Evans *et al.*), 1230
Walker, C. T., and Dennis, Prof. J. G . Explosive Phase Transitions in the Earth's Mantle, 182
Walker, Dr. G. P. L., and Gass, Dr. I. G. : Volcanology Research in New Zealand, 1077
Walker, J A. J. : Chromatographic Separation of Argon and Oxygen using Molecular Sieve, 197
Walker, Dr. R. T., *et al* : Use of Acidic Degradation for the Determination of the Distribution of Pyrimidine Nucleotides in Deoxyribonucleic Acids, 296
Walker, Dr Richard V., Barnes, Dr M. G , and Higgins, E. D : Composition of, and Physiopathology produced by Plague Endotoxins, 1246
Walker Tumour 256 in Rats : Failure of Methylcellulose to alter the Growth of (Dr. A. W. Lazar *et al*), 1140
Wall Teichoic Acid, Changes in, resulting from Mutations of *Staphylococcus aureus* (Dr M J. Wolin, Dr. A. R Archibald and Prof. J. Baddiley), 484–6
Wall Thickening in *Callitris glauca* R BR. (G. W Davies and H D. Ingle), 826
Wallace, Prof. A., Frolich, E., and Lunt, Prof. O. R. : Calcium Requirements of Higher Plants, 634
Wallace, Dr. G K., Gregory, Dr. R. L : Optical Illusions, 327
Wallace, Stanley L., *et al.* : Renal Handling of Glycine in Primary Hyperuricaemia, 213
Wallbank, Prof. Alfred M , Sperling, Prof F. G., Hubben, K., and Stubbs, Prof. E. L. : Isolation of a Tumour Virus from a Chicken submitted to a Poultry Diagnostic Laboratory–Esh Sarcoma Virus, 1265
Wallis, Dr. R G . *Obituary* of Dr B R Record, 855
Walsby, A. E , and Fay, Dr P. : Metabolic Activities of Isolated Heterocysts of the Blue-Green Alga *Anabaena cylindrica*, 94
Walshe, Sir Francis : *Obituary* of Sir Gordon Morgan Holmes, 853
Walter, Prof. Charles : Oscillation in Enzyme Reactions, 404
Walter and Eliza Hall Institute, Melbourne : Appointment of Head of the Experimental Pathology Department, 1177
Walters, Dr. V , *et al* . Influence of Incubation Temperature and of Storage on the Viability of Fungal Spores damaged by Phenol, 106
Walton, G S., and Rook, A. J (edited by) : Comparative Physiology and Pathology of the Skin, *review* by Prof C D Calnan, 9
Wang, Prof. C. H., and Willis, Prof D. L. Radiotracer Methodology in Biological Science, *review* by Dr. J. R Catch, 5
Wang Loong-Seng, *et al.* : Emission Band Systems of Ag_2 produced in Discharge, 1300–2
Ward, Eileen E. : Uptake of Plutonium by the Lobster *Homarus vulgaris*, 625
Warm Climates : Building in, 1073
Warren, Dr. Kenneth S., and Weisberger, Prof A. S. : Suppression of Schistosomiasis in Snails by Chloramphenicol, 422
Warrington, Richard L , *et al* : Naturally Occurring Foetal Haemoglobin Hybrid, 721
Washington : Philosophical Society of, 564
Waste-handling Problems Solution to, 136
Water Consumption in the Rat . Effect of Chlorothiazide on (Dr. J. Gutman and M. Chaimovitz), 410
Water Drops Effect of Carbon Dioxide on the Shattering of Freezing (J. E. Dye and Prof P. V. Hobbs), 464–6
Water and Electrolyte Changes in Cardiac and Skeletal Muscle of Cats Late in Haemorrhagic Shock (Prof E D Brand), 814
Water Jet : Surface Entrainment of Air by a (A T. Sheridan), 799
Water Properties and the Growth of Bacteria Correlation of Temperature-dependent (Prof C B. Davey and Dr. R. J. Miller), 638
Water Resources in Britain, 1182
Water Resources . South-East England, 247
Water at 2.93 μ and Water Content of Black Foam Films : Extinction Coefficient of (Dr J. S Clunie *et al.*), 1192
Water Vapour . Effect of Temperature on the γ-Radiolysis of (Dr. A. R. Anderson *et al*), 199
Waterman, Prof Talbot H., and Morowitz, Prof. H. J. (edited by) : Theoretical and Mathematical Biology, *review* by Dr. I J Good, 1164
Waters, E H , and Moss, G F. : Estimation of Moisture Content by Neutron Scattering : Effect of Sample Density and Composition, 287
Waters, Dr. W. A. : Zahlenwerte und Funktionen aus Naturwissenschaften und Technik (Landolt-Bornstein) Neue Serie, Band I, *review*, 1164
Watkins, P J , and Herberg, Dr. L J : Epileptiform Seizures induced by Hypothalamic Stimulation in the Rat : Resistance to Fits following Fits, 515
Watson, Ann, and French, C : Muller-Lyer Haptic Illusion and a Confusion Theory Explanation, 942
Watson, Dr. D H., *et al.* : What's in a Virus Name? 450–4
Watson, Dr. H. C., *et al.* : Structure of Deoxymyoglobin : A Crystallographic Study, 339–41
Watson, Dr. W. F. : Encyclopedia of Polymer Science and Technology, Vol. 2, *review*, 338

Wavefront Reconstruction · Dual- and Multiple-beam Interferometry by (Dr. J. M. Burch *et al*), 1015
Waves by Cooling . Attenuation of Shock (J C Muirhead), 64
Waves : Reflectivity of Atmospheric Shock (W. R. Mallory), 175
Waves Scattering of Electromagnetic Waves by Electro-acoustic Plasma (P F. Little and S. M. Hamberger), 972–4
Waxes : Crystallization of Petroleum (Dr. B. F. Birdwell and Prof. F. W. Jessen), 366–8
Waxman, Bruce D , and Stacey, R W. (edited by) : Computers in Biomedical Research : Vol I, *review* by Prof P. Armitage, 233
Wayne, R. P , et *al.* : Effect of Zinc Chloride on the Velocity Coefficients in the Polymerization of Methyl Methacrylate, 292
Weatherall, R. : Assessment Procedures in Secondary School Science, 357
Social Influences on Measured Intelligence, 1298–1300
Webb, G. N., and Brown, Prof. C. C. : Instrumentation with Semiconductors for Medical Researchers, *review* by Dr. J. R B Greer, 333
Webster, Dr. H. L , *et al* Electrophoresis of the Soluble Proteins of Wheat Leaf, 1133
Weimer, Prof. H. E , and Benjamin, D. C. : Synthesis of α_2-AP (Acute Phase) Globulin of Rat Serum by the Liver, 1032
Weintraub, Dr. Ronald M , and Crisler, C · Complement Fixation and *p*H, 1035

Pye precision in gas chromatography

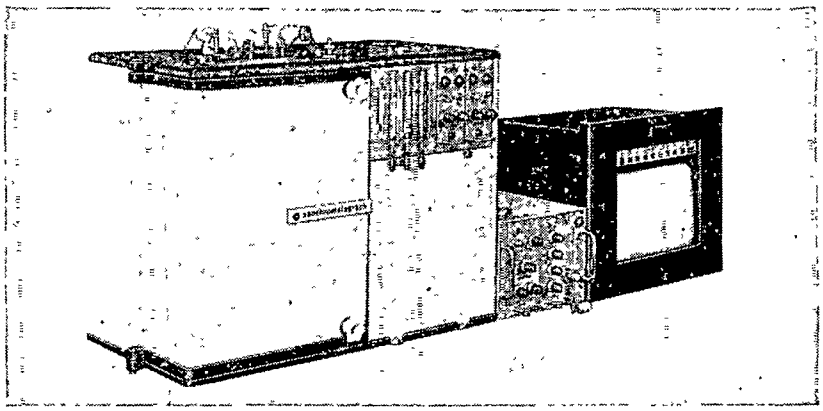
Oven accommodates interchangeable head units incorporating different detector and column configurations and is designed for isothermal or programmed temperature control.

Oven head unit with dual flame detectors, columns and injection ports

NEW PYE SERIES 104 CHROMATOGRAPHS SPEED ROUTINE ANALYSES

Analysts are changing to the new low-cost Series 104 Chromatograph because its greater speed and convenience save money. They have acknowledged the functional design, the simplified operating features, the comprehensive specification and the overall economy of the system. They are now experiencing its complete reliability under continuous operating conditions.

Four versions of Series 104 are available which cover everyday analytical applications, including steroids, fatty acids, wide boiling range mixtures and high boilers.



The Pye Series 104 Chromatograph gives *faster analysis* with warm-up rates of up to 48°C per minute and operating temperatures as high as 500°C, *easier analysis* due to excellent oven accessibility and design of controls, and *cheaper analysis* with lowest possible outlay and maintenance costs.

Moreover, the Pye Series 104 is designed for continuous development and updating as new techniques emerge.

Please send for the new 20 page illustrated brochure which provides all the technical facts and figures including oven performance data.

PYE PANCHROMATOGRAPHS AID RESEARCH

Leading research establishments in many parts of the world depend upon the versatility of the Pye Panchromatograph to satisfy their most stringent requirements including investigations into the technique and the teaching of gas chromatography. This analytical system can accommodate different detector combinations and column arrangements in two independent ovens, and it features a patented column effluent splitting device which permits further analysis of the column outputs. Numerous optional features including temperature programming, pyrolysis, preparative scale and radiochromatography are available. The Pye Panchromatograph is the first choice for an all-purpose instrument for research.

The Panchromatograph will accommodate six different types of detector, singly or in pairs.

STABILIZING THE RESEARCH EFFORT

IN its summer issue, devoted to the subject of "Creativity and Learning", *Daedalus*, the journal of the American Academy of Arts and Sciences, introduces a new section, entitled "Documents". This includes Prof. J. B. Kistiakowsky's "On Federal Support of Basic Research", which originally appeared as part of an investigation undertaken by the American Academy of Sciences at the invitation of the Committee on Science and Astronautics of the United States House of Representatives. This is a thoroughly pragmatic discussion of the relations between pure and applied research and is the more interesting in the light of a report on "Basic Research and National Goals" made by the Academy of Sciences to the same Committee, which has now been published in a corresponding section of the Summer 1965 issue of *Minerva*.

Prof. Kistiakowsky begins by referring to the serious danger created by the increasing spread of the idea that basic research can be planned in detail, and that money need be allocated only to specific topics in order to provide the necessary scientific knowledge for the advance of technology. Citing as examples the discovery of the laser and the maser, the relations between genetics and chemistry in molecular biology, and the impact of high-polymer research, he points out that, on the contrary, while clearly defined mission-oriented research has value, by itself it is insufficient and is incapable of developing really new ideas and new principles on which each particular mission will ultimately be based. If the social climate and the mechanisms of support do not rapidly and effectively encourage the free exploration of new ideas, technology will die on the vine because, in the absence of the results of new, undirected basic research, applied work tends to become confined increasingly to expensive refinements and elaborations of old ideas.

Prof. Kistiakowsky points out that scientific activities and their financial support cannot continue to grow indefinitely at the present pace. Nevertheless, it is in the nature of technology not only to solve human problems, but also to generate new ones. Here he is thinking more especially of the human and social problems which arise and, while he insists that the major problems of humanity will not be solved by technological innovations (educational and other social progress being probably more important), he concludes that we need a better understanding of relevant social and behavioural problems and consequently more research in these sciences. The progress of human society must be based on social change keeping pace with technological progress.

Prof. Kistiakowsky goes on to discuss the criteria for determining fiscal support of scientific research. Basic research, he estimates, accounts for only a few tenths of 1 per cent of the gross national product of the United States. Expenditure on research and development, however, is estimated at nearly 20,000 million dollars—some 90 per cent of this being expended on efforts to achieve specific practical objectives, many related to the military and space programmes. Fewer than 100,000 scientists are engaged in basic research out of a technical community of more than 2 million engineers and scientists. It is at this point that Prof. Kistiakowsky considers the two distinct questions posed by the House Committee on Science and Astronautics, which are the subject of the reports of Prof. H. G. Johnson and Dr. A. M. Weinberg in *Minerva*: the requirements for overall support of basic research and the proper balance of support among the several sciences. He approaches both questions by dividing basic research into four categories and suggesting a basis for criteria of support for each.

His first category is characterized by the small size of its constituent autonomous research units, in contrast with his second category which involves large co-ordinated effort, and usually very costly research facilities as well. Both these categories are mainly identified with academic institutions. His third category is basic research in mission-oriented Government establishments, and his fourth in industrial laboratories. He regards projections for a break-down by separate sciences as well-nigh impossible and adds a caveat that the purpose of planning for science is to chart in advance the evolution of a scientific environment and climate in which innovation and creativity can flourish.

About 57 per cent of research in the first category is supported by grants and contracts from the Federal Government to universities, and although Prof. Kistiakowsky estimates that less than 100,000 people are engaged on a full-time basis, it is responsible for great contributions to scientific knowledge, as well as for training most of the new scientists. The 7,000 or so Ph.D.s in science now being produced annually—a figure growing by 6 or 7 per cent each year—are responsible for research work costing on average perhaps 15,000–20,000 dollars per annum per man, and he makes the interesting comment that more should be expected from research institutes or laboratories in scientific output if, unlike the universities, they do not contribute to the training of new manpower. On the financing of such work by large contracts or block grants, he emphasizes the danger that this method can lead to distinctly second-rate or poor research being hidden and protected by the good work of a few leaders.

The costs of scientific research are steadily increasing, partly because the problems are becoming more difficult; although, on the other hand, because of efficient instruments, problems that formerly appeared formidable can sometimes be solved in days instead of years. As to the criteria for determining actual expenditure in this category, he suggests first that, since continuity is important, effective expenditure in the past year should be a large factor in deciding expenditure in the next. The second, he suggests, is to assure future students with scientific aptitudes of the opportunity to learn productive research. His third suggestion concerns the level of support in the rest of the world—a criterion which, if valid for the United States, is open to question for most other countries. He believes that more basic research is needed across the whole range of scientific fields, including the behavioural sciences, and to meet this need he tentatively suggests an overall growth of 15 per cent over the next 5–10 years, which would double by 1968 his estimate of a total 600 million dollars in 1963.

As to the allocation of the total to individual problems, he insists that every effort should be made to minimize detailed centralized planning and control. The detailed

allocation of support should be based on the multitude of individual choices made by individual investigators.

The proper rate of growth in his second category should be determined by other considerations, and here he is largely guided by Dr. Weinberg's observations in an earlier article of 1963. In this field the commitment of scientific personnel per project is rising comparatively slowly and costs are concentrated in the engineering effort of constructing the special facilities required, and in their maintenance, operation and improvement. Nevertheless, the cost for each active scientist or scientific paper is very much higher than in his first category, and Prof. Kistiakowsky suggests that, before weighing seriously the comparative value of a new project in this field, it is essential to verify that it is technically feasible in the judgment of engineering experts and that a qualified group of scientists regard it as important enough to warrant support with firm personal commitments.

Beyond this, Prof. Kistiakowsky would, like Dr. Weinberg, give some weight to the impact of a given type of research on related and significant branches of science and to its impact on practical application. He does not entirely reject the factor of national prestige and international influence, and feels that the broad cultural impact of scientific research is less susceptible of quantitative evaluation, although he attaches some importance to it in the particular fields of galactic astronomy, molecular genetics and high-energy physics. Judgments, however, are fallible and should, he points out, be in terms of various degrees of value. He believes that this category of research should not grow at the expense of his first category but is undecided whether it should grow more or less rapidly than the latter.

While firmly endorsing the need for, and value of, mission-oriented research, he has important reservations about the introduction of general basic research into Government establishments and regards the substitution therein of such research for mission-oriented research as unsound both from the scientific and the economic points of view. Much the same considerations, he believes, should apply to his fourth category—that of research financed by the Federal Government in private industrial research laboratories. He would accordingly relate such research to practical objectives and it would seem that he would have some reservations about the grant-aided industrial research association as practised in Britain. For all his conviction that basic research requires support over the whole spectrum of sciences, he is emphatic that the main justification for Federal support on the present scale lies in its practical application of benefit to the nation.

The first of the two reports in *Minerva* is concerned with some economic issues involved in the Federal support of basic research. Prof. Johnson accepts that some meaning can be attached to the distinction drawn between basic and applied research, though it is not so much the imprecision of that distinction as the extreme uncertainty of both the contribution to knowledge resulting from a particular line of research and the ultimate practical utility of that contribution which is the main source of difficulty in formulating public policy with respect to basic research. He sees, however, no necessary connexion between leadership in basic science and leadership in the applications of science: there may indeed be conflict between basic research and applied science. The two main arguments for Government support of science are cultural–social and economic.

Prof. Johnson examines both these arguments: the latter at some length. The former emphasizes scientific activity as a form of social consumption of wealth and raises the political question of whether other uses of the resources involved would contribute more to the greatness of the society. Accordingly, the decision cannot be left to the scientist alone. The economic argument regards scientific research as a form of investment for the future and raises the questions of what the rate of return on such investment is, and whether and to what extent Government support is needed.

Economic research has so far provided few relevant results. Prof. Johnson points out that there are good theoretical reasons for expecting that, left to itself, the market would tend both to allocate too few resources to research in general and to prejudice the allocation against basic research as contrasted with applied research, and towards research in scientific areas related to the technology of industries dominated by large multi-product firms. This expectation seems to be substantially confirmed by the industrial distribution of expenditure on research and development. (The analysis, incidentally, offers an explanation of the lack of research effort in the smaller firm.) This discussion, moreover, brings out several important questions to which answers should be sought before firm conclusions can be reached. These relate to the extent or the distribution of support of basic research. For the latter, such questions arise as the likelihood of proposed new lines of research producing new contributions to knowledge and the possible social value of these contributions in relation to their cost; and the probability of any particular project being undertaken elsewhere, and the consequences. The former raises questions as to the rapidity with which returns on research diminish; how far increased expenditure on research increases the quantity of research results and how far it merely raises the operating costs.

There is also the final question of the extent to which Government support and private support of basic research are substitutes for one another. Answers to all these questions are necessary to judge the adequacy of Federal support of basic research from the economic point of view. Prof. Johnson does not attempt to provide a firm answer to the question of the amount and distribution of such Federal support. He is content to emphasize the dangers attending any answer in the absence of further and firm knowledge which might provide answers to the subsidiary question. He directs attention to the importance which the United States attaches to the geographical distribution of support and urges that so long as public funds are allocated to basic research, the geographical allocation of those funds should take account of the social effects of their expenditure—an argument which, to a limited extent, appears to be reflected in some of the recent regional plans for Britain's economy.

Dr. Weinberg, in contrast, addresses himself primarily to the question of scientific choice in both basic science and applied missions, and while he admits his indebtedness to Dr. Toulmin's paper on this subject (see *Nature*, 205, 426; 1965) he largely follows his own earlier exposition (*Nature*, 200, 503, 1030; 1963). He reiterates, for example, his distinction between political choices and administrative choices and emphasizes the importance of making choices between political alternatives and administrative alternatives; this factor, rather than the question of who makes the choice, is the key problem. He insists once again on the prior need to separate

research pursued for non-scientific ends from that pursued to further science. He also regards it as essential that each mission-oriented agency should assume the responsibility for supporting basic science in fields generally relevant to the agency's research and at a level bearing some relation to the size of its budget for applied science. It is beyond this level that the National Science Foundation should assume responsibility for supporting basic science where necessary.

Dr. Weinberg does not really answer the question of how to allocate support for basic science, other than by proposing a pattern of organization to handle the allocation, and he has little fear that to place the motivation for supporting basic research mainly on the hope of some eventual benefit from its application will result in basic research being unduly curtailed in time of falling budgets. Furthermore, for all the reliance he places on the National Science Foundation for securing a sound distribution of the national expenditure on basic research, he is convinced that such support should be drawn from numerous sources, and not just one or two. Nevertheless, he is opposed to any expansion of basic physical research merely to further the objectives of, for example, the Atomic Energy Commission, the Department of Defence, or the National Aeronautics and Space Administration.

The relevance of these views to discussion on expenditure on civil research in Britain, for which the new Council for Scientific Policy has recommended some £54 million a year, with a continuing growth for five years at the same rate as in the past decade, or 15 per cent per annum, is obvious. However, before considering specific implications to complete the picture we may appropriately note Dr. Weinberg's further observations in a paper, "Government, Education and Civilian Technology", which he contributed to a Seminar on Technology and Social Change at Columbia University. This paper has now been published, together with the other six papers, an introduction by C. Wright, notes on the discussions on each paper, and a summary by A. W. Warner, under the title *The Impact of Science on Technology* *. Some of the points which Dr. Weinberg makes here concern the dangers inherent in the reform of curricula in universities unless the reforms are in the hands of men of wide outlook sympathetic to applied science and resistant to the fragmentation of science. Otherwise we may continue to produce graduates with little sympathy outside their own special field, who are thus less competent for technological research. He repeats his warning that the value of the by-products of military research and development tends to be exaggerated and that civil industry should not rely to any extent on such 'fall-out'. He reiterates his concern at the consequences of neglecting areas of the scientific field because they are less fashionable and emphasizes the importance of scientists paying due attention to the social implications of their work.

In the first two papers presented at the symposium, Prof. I. I. Rabi and Dean Harvey Brooks contribute differing views of the interaction of science and technology. Prof. Rabi questions the effect of science on older industry until the latter has developed to a very sophisticated degree: the more important effect has been to create new industries, and supply, along with new knowledge, new components and new techniques. An important factor in the growth of industry and technology has been the adoption of instruments originally developed for scientific advance itself. He questions, however, whether the cultural climate in the United States really encourages the originality and eccentricity which often mark the innovator. On the other hand, it does encourage team work, the value of which he firmly acknowledges. Like Dr. Weinberg, he is equally emphatic, while emphasizing the dependence of the future of society on science, that the scientist should be concerned with society and the arts, if only for their contribution to imagination and inspiration. In the discussion he adds, too, a warning against the assumption that increasing the number of scientists is likely to increase proportionately the number of outstanding people.

Dean Brooks disagrees to some extent with Prof. Rabi as to the factors promoting innovation. He regards the role of science in the development of technology as being to provide the environment in which technological ideas can be exploited, rather than being itself the origin of technological ideas. The same qualities of mind go into science as go into invention, and whether a man will be an inventor or a scientist is determined by his emotional attitude to the subject. While the same qualities that go into invention may also go into the creation of new techniques, emotionally the two activities are poles apart. Accordingly, while the creation of new science is necessary, it is not a sufficient condition for creating new technology.

Without convincingly establishing this view, Dean Brooks lists several factors conducive to technological innovation which originate in science and are highly pertinent to the consideration of the expansion of higher education in Britain, as well as to that of the scale and distribution of British scientific effort. First and most important is widespread scientific literacy. Next he places the creation of a scientifically literate management with an instinct for possibilities in the technical area. It might be interpreted that this is a first condition for the effective distribution of our scientific effort in general and for informed discussion of structure and distribution. This is especially so in view of the fact that the House of Commons, in debating on October 27 the report of the Select Committee on Procedure, slammed the door on any such idea, in spite of the recommendation from the Parliamentary and Scientific Committee.

Thirdly, he puts mobility among the intellectual disciplines, and firmly condemns specialization as the enemy of technological innovation. He adds that application of science often arises from the movement of people from basic science into technology—a point of view which may well lie behind Prof. Rabi's belief in the value of team work. Like Prof. Rabi, when emphasizing the great importance for innovation of the diffusion of graduates from science into technology, Dean Brooks suggests that some over-production of scientists may be an essential condition of continuing technological innovation. Put in another way, this amounts to condemnation of the practice of regarding university education or technological education as primarily professional training for a particular occupation instead of being aimed at producing educated men and women competent to apply themselves to a range of professional occupations.

Here again we note the emphasis on the social aspects and on the vital importance of a broad-based education. Moreover, there is a limit, which should be noted, of the effect of science and technology on institutional innovation. This recurs to some extent in a fourth paper from F. de Hoffmann on "Advanced Technology and American

* *The Impact of Science on Technology*. Edited by Prof. Aaron W. Warner, Dean Morse and Alfred S. Eichner. Pp. vi+221. (New York and London. Columbia University Press, 1965.) 50*s*.

Business: Friends or Foes?" He is mainly concerned with questions of management and organization, for while he holds that creativity and organization can be harmonized in group or team efforts, creativity and regimentation cannot. Again, therefore, we find emphasis placed on the importance of wise management in organizing interdisciplinary effort and, by implication, on the broad general education which promotes scientific understanding in the management field. One constructive suggestion that he makes is that decisions regarding large-scale research and development should be the responsibility of several centres rather than one alone, and that industry should co-operate with Government to that end. The importance of entrusting responsibility to technical people could not be more strongly emphasized, nor indeed could the value of ensuring that the scientist works in an atmosphere conducive to creative work, with the assurance that problems, so far as possible, are approached in a scientific manner.

Mr. de Hoffmann's paper is full of warnings that the conditions for effective scientific work must be respected, and much of the paper is in line with the views of Dr. Stoll. Nor does he offer much support to the idea of the co-operative research association in industry. A further paper, from Mr. J. H. Hollomon, on "Science and the Civilian Technology" directs attention to some relevant developments in the social and economic structure of the United States of which account must be taken in any planning in this or in any other field. He, too, emphasizes the limitations which are placed on technological advance by any lack of those who understand both science and technology on one hand, or, on the other, the business aspect of a technological enterprise. His most serious warning, however, concerns the high social cost of technological change, and the importance of the adequate use of technology in decision-making at all levels.

The remaining two papers are much more clearly concerned with the American scene. Mr. J. Brademas sets forth a Congressman's view of technology and social change, but Dean R. S. Halford's paper on modern science and its implications for the university, while largely concerned with the effect of the increasing scale of Federal support for research in the American universities and the way this is being handled through the formation by a group of universities of non-profit corporations, has some interest for the organization of research in Britain. As a further safeguard against possible distortion of the work of a university through Federal grants for research, Dean Halford stresses the firm insistence on the recovery of all indirect costs related to the conduct of research sponsored by Government agencies, and the need to relate requirements for a faculty to the instructional requirements of the teaching programme.

Some of the points raised in the seminar which are most pertinent to present-day debates in Britain are well brought out by Prof. A. W. Warner in his summing up. He does not, however, mention the fact that within the previous 6 months Columbia University had found itself under-spending funds committed to it for research, just when, in the United States generally, the level of expenditure on research was being questioned. This may well be relevant if, in fact, the growth of expenditure on research in Britain is to be checked under the Government's plans. Conditions in the two countries, however, are not parallel and much clear thinking will be required if short-sighted curtailment of expenditure on basic research is not to do serious harm. That there are definite limits to the amount which any nation can wisely expend on scientific research is not disputed. How that limit is to be determined, and still more, how the amount available should be distributed among the different fields are other questions altogether; it is obvious from the papers noted here that the United States is still seeking for answers to these.

What should be evident, so far as Britain is concerned, is that she is as yet a long way from the limit. In the social sciences and in education in particular expenditure on research is trifling, and far short of what the national interest demands. That is also largely true of research in the physical sciences which bears on the utilization of natural resources. Here, for example, the Government's reported decision to hold up the pilot studies on the Solway and Morecambe Bay barrage schemes on the excuse of economy is disturbing and indicates the persistence of the 'penny wise, pound foolish' attitude for which Britain has paid dearly in the past. For all the protestations of the present Government and its predecessor, it is hard to point to any imaginative and far-sighted decisions which indicate an awareness of the potential contributions which scientific research could make in Britain's economy, or readiness to take the action demanded by the fact and not that demanded by party prejudices. However low the level of expenditure on fundamental and applied research may be set, it will still call for sacrifices elsewhere. Scientists are unlikely to be convinced that any Government is really prepared to support such expenditure on an adequate scale while the present attitude of the Ministry of Technology persists.

THE ACHIEVEMENTS OF LORD RAYLEIGH

Scientific Papers

By Lord Rayleigh (John William Strutt). Vol. 1: 1869–1881. Pp. xiii+562. Vol. 2. 1881–1887. Pp. x+598+16 plates. Vol. 3: 1887–1892. Pp. xiv+596. Vol. 4: 1892–1901. Pp. xiv+568. Vol. 5: 1902–1910. Pp. xvi+624. Vol. 6: 1911–1919. Pp. xiii+718. (New York: Dover Publications, Inc.; London: Constable and Co., Ltd., 1964.) 30 dollars; 240*s*. The six volumes bound as three.

LORD RAYLEIGH was a man whose range of research in the world of physical science has, it may be ventured, no equal among those active at the present time. In the first place, he was equally distinguished for his work in the mathematical field and for his experimental achievements. In the second place he made notable advances in all branches of what is known as classical physics: heat, light, sound, properties of matter, magnetism and electricity—and in chemistry too, if we consider the leading part which he played in the discovery of argon.

To mention but a few contrasting accomplishments, he made a fundamental experimental re-determination of electrical standards and wrote what is still a standard book, containing much of which he was the originator, on sound; certain advances which he made in wave theory explained the blue of the sky and others contributed to the study of earthquakes; he was equally authoritative in hydrodynamics and thermodynamics; he gave a celebrated presidential address to the Society for Psychical Research and took a leading part in the foundation and early administration of the National Physical Laboratory. These odd citations suffice, perhaps, to revive memories of his varied mastership.

His collected *Scientific Papers* were originally published in six large quarto volumes by the Cambridge University

Press, the first volume having appeared in 1899 and the final one, posthumously, in 1920. Rayleigh made an amusing comment in connexion with the publication of the first volume: "When I was bringing out my *Scientific Papers* I proposed a motto from the Psalms, 'The works of the Lord are great, sought out of all them that have pleasure therein'. The Secretary to the Press suggested with many apologies that the reader might suppose that *I* was the Lord." This, no doubt, is the reason that, while the scriptural quotation is used, it appears not on the title page but in isolation on a separate page just before the first paper.

The atmosphere of the great age of classical physics to which these papers pertain may be recalled by reference to the name index which appears at the end of the final volume. Citations, merely page numbers, of Stokes occupy 13 lines, of Maxwell 12, of Kelvin 11, of Helmholtz 9, of Lamb 7 and of Airy 5 lines—a formidable company.

These collected papers are still constantly used for reference, since, among other things, when Rayleigh had written at length on a subject he had, in general, tidied it up and left it in a state clearly recording the position at the time. One can scarcely do better than quote J. J. Thomson's pronouncement: "While most collections of scientific papers rest undisturbed on their shelves, and are monuments, rather than parts of one's working library, there are no books I refer to so frequently as Rayleigh's collected papers. His papers deserve the description, which Maxwell applied to those of Ampère, as being 'perfect in form and unassailable in accuracy'. The style is very clear, so clear in fact that the reader may not realize how difficult the problem was unless he had attacked it himself before reading the paper".

The original issue of the *Scientific Papers* has, with the exception of Volume 6, been out of print for some time. Fortunately a re-issue of the six volumes, bound in pairs so as to make three books, has recently been published at a very reasonable price. The text would appear to have been reproduced by a photographic process, since whenever a page has been compared with the original the two are exactly the same. However, the introduction states that the edition is an unabridged and corrected republication of the work first published by the Cambridge University Press, which would seem to imply that there have been changes, if minor ones.

This new edition contains an interesting supplement of photographs pertaining to Rayleigh's life—portraits, pictures of his laboratory, of pages from his notebook, and so on. A great improvement could have been effected by the provision of a serviceable index. There is a name index, which suffers, as is so often the case, from a lack of the slightest indication as to what is in question under each of the large number of pages listed under a given name; more than a hundred, for example, in the case of Maxwell. There is no subject index at all, unless the list of titles of papers, grouped under twelve different headings, such as "Mathematics", "General Mechanics", "Elastic Solids", and so on, can be so called. This list, however, is not very useful if one desires to find quickly what Rayleigh has written on a particular subject: thus the only references to argon are in the titles of certain papers listed under the heading "Properties of Gases", but there is no indication that the viscosity of argon is considered in papers listed under "Dynamical Theory of Gases". Possibly the publishers will contemplate adding to the value of this welcome reprint by issuing in a small supplementary volume a detailed index giving not only a properly classified subject schedule but also a name index with some indication as to what, to take an example, is concerned in each entry under the name Maxwell. The preparation of such an index, which would require considerable knowledge and study, might possibly qualify a student for a degree in the history of science.

E. N. DA C. ANDRADE

A ROUTE MAP THROUGH THE SPECTRAL LABYRINTH

Atlas of Steroid Spectra

By W. Neudert and H. Röpke. Translated by J. B. Leane. Pp. viii+471. (Berlin, Heidelberg and New York: Springer-Verlag, 1965.) D.M. 144.

THE advent during recent years of various sophisticated, physical techniques, as an adjunct to structural investigations in organic chemistry, has led to its own special problems. In particular, the data thus accruing are frequently very difficult to locate in the literature and, for a variety of reasons, are often of doubtful comparative value for the identification of closely associated compounds.

Nowhere is this problem more acute than in the vast literature appertaining to the steroids. The *Atlas of Steroid Spectra* is a gallant and monumental attempt to bring some rationale into an otherwise confused situation. The production of this weighty (in both senses of the word) volume was undertaken because the majority of existing steroid spectra originated from various sources, and therefore could not be compared with each other directly. The great merit of this volume, which has been produced with typically Teutonic attention to detail and accuracy, is that it records the spectra of 900 specially selected steroids. The samples were prepared under directly comparable conditions and the spectra measured on the same instrument in order to ensure that the results are directly comparable. The information recorded in this *magnum opus* has been accumulated during the past twelve years, which the authors have spent in the structural investigation of steroids.

The first section includes the infra-red spectra and other relevant physical data, such as molecular weight, melting-point and characteristic ultra-violet absorption maxima for 900 steroids. Then follow various typical ultra-violet absorption curves for 41 representative steroids. The third section records the nuclear magnetic resonance spectra of 95 steroids. The remainder of the book consists of chapters concerning the relevant theory and the methods by which these various spectral determinations may be performed, together with a veritable wealth of associated information such as, for example, the effect of temperature on spectra. The final section of the book contains the basis of a versatile catalogue system for recording the detailed spectral information.

A most useful feature of the *Atlas* is that the German text has an English translation alongside.

This book is essentially a handbook or dictionary, which will serve as a most valuable reference work for all research laboratories. By nature of its size, price and content, it is scarcely likely to appeal to the individual purchaser. A particularly noteworthy feature of this *Atlas* is that it is based entirely on work carried out in the laboratories of an industrial company, namely, Schering *A.G.* (Berlin). Its authors, to whom all steroid chemists owe an immense debt of gratitude for their painstaking effort, are also employed by the same company.

This book maintains the extremely high standard which has been established by its publishers. W. B. WHALLEY

RADIOACTIVE TRACER TECHNIQUE IN BIOLOGY

Radiotracer Methodology in Biological Science

By C. H. Wang and D. L. Willis. (Biological Science Series.) Pp. xvii+382. (Englewood Cliffs, New Jersey and London: Prentice-Hall International, 1965.) 96*s*.

RADIOTRACER Methodology in Biological Science is an excellent book. Radioactive tracers are commonplace and indispensable in research laboratories, but their

experimental methods find little place as yet in teaching courses. There must be many readers who need reliable, sensible and up-to-date information and guidance, and they will be grateful to Profs. Wang and Willis for providing it.

The authors write that "the organization of the text stems both from the authors' research interests and, more importantly, from teaching experience involving students from the various fields of biology". This is apparent from the choice and treatment of the material.

The first and largest part of the book (266 pp.) deals with the origin and basic properties of radioactive materials, methods of detection and other practical considerations. The treatment is clear, systematic and concise. The typical reader, who may have little or no acquaintance with radioactive tracers, will find it well suited to his needs, both for instruction and as a first book of reference. Proper emphasis is laid on the best techniques at present available in a well-equipped laboratory, but older or simpler methods, which are still in use or which teach important principles, are also adequately treated.

The second part (44 pp.) consists of basic experiments in the measurement of radioactivity. It covers Geiger, proportional, solid-scintillation and liquid-scintillation counters, the nature of radioactivity decay, and interaction of radiation with matter.

The final section (56 pp.) is, in some respects, the most interesting. It comprises six illustrative radiotracer experiments, selected for the likely interests of the reader; these are: "Incorporation of $^{14}CO_2$ into Amino Acids in Yeast"; "A Time Course Study of $^{14}CO_2$ Production from Rats Metabolizing Glucose-^{14}C Substrate"; "The Effect of X Irradiation on Bone Marrow Activity in Rats as Measured by Iron-59 Incorporation into Erythrocytes"; "An Investigation of Sodium Ion Regulation in Crayfish using Sodium-22"; "Determination of Coefficients of Zinc-65 Accumulation in Freshwater Plants"; "Determination of the Content of Aspartic Acid in Cheese by Means of the Isotope Dilution Method". Each is worked out quite thoroughly, using the information and methods given earlier in the text: for example, survey of the problem; experimental design (scale and requirements for radioactivity); materials and equipment required; experimental procedure; experimental notes. Questions interpolated here and there will help to keep the student aware of what he is doing, and why.

The bibliographies for the various chapters are good, and there is an adequate index. The book is well but not extravagantly produced.

There are a number of specific points about this book which I liked. The English style is clear and readable. The text abounds in brief, commonsense observations which attract attention and set the reader on the right lines: "autoradiography is as much an art as a science"; "proper preparation of counting samples is as important—as the counting operation"; "radiotracers must always be regarded as only a tool, not a panacea"; "the investigator must take an open-minded, unprejudiced approach—"; "the opportunities for misinterpretation are probably much greater (in tracer experiments) than in the traditional approaches". I can endorse the validity of these and of many similar observations, and the need to present them and to insist on them, even at the present date.

The selection of material shows also that the authors are looking forward and not backward. The technique of 'radiorespirometry' (kinetic studies of respiratory metabolism, detecting $^{14}CO_2$ from suitably labelled substrates), patiently promoted for some years by a handful of enthusiasts, is still in very limited use, and good equipment is still rare and expensive. Profs. Wang and Willis give it nevertheless a fairly thorough treatment, as a method of which every serious student should have some knowledge.

Inevitably, I found details with which I do not agree, but they are not important enough to be discussed in a review of this size

The price may appear rather high to readers in Britain, but for a book of this kind and standard it is reasonable.

John R. Catch

CRYSTALLOGRAPHY: TRANSLATION OF A RUSSIAN DATA COMPILATION

Handbook of X-ray Analysis of Polycrystalline Materials

By Lev Iosifovich Mirkin. Authorized translation from the Russian by Dr. J. E. S. Bradley. Pp. xx+731. (New York: Consultants Bureau, 1964.) 35 dollars.

HOW different the appraisal of the English edition of Dr. Mirkin's *Handbook of X-ray Analysis of Polycrystalline Materials* must be from that of the original Russian text of 1961 is shown by Prof. Ya. S. Umanskii's remark, in the foreword, that apart from Kitaigorodski's classical compilation of twenty years earlier this was the only general reference work on X-ray analysis published in the U.S.S.R. In the English language it is with a bookshelf already containing the *International Tables for X-ray Crystallography* and other well-known specialized compilations that we must judge the usefulness of any new compilation.

Dr. Mirkin's book is divided into two roughly equal parts entitled "General Methods of X-ray Structure Analysis" and "Some Special Problems and Methods in X-ray Structure Analysis". These titles would be thoroughly misleading were it not for the overall title, Part 1 in fact being directed towards the powder method, and Part 2 mainly concerning identification, accurate measurement of structure cell dimensions, and certain extra-structural features.

In choosing the order of presentation in Part 1, the author has borne in mind the sequence of events in an analysis. Thus we find that X-ray wave-lengths, absorption coefficients and similar data come first. A short survey of the main types of Russian equipment (*c.* 1961) is also included and nomograms and charts are provided to facilitate the setting up of cameras and monochromators.

Having, so to speak, obtained diffraction data, one arrives at tables relating Bragg angles with ring diameters for a range of specimen-to-(flat)film distances. If a cylindrical camera is used then corrections for specimen eccentricity and thickness are here to hand. The usual extrapolation functions, however, are kept for a chapter in Part 2 and it is only by browsing that one finds them—the index being of little help. Commendably, charts for $\theta - d$ conversion have been omitted, these being available in a more suitable larger format elsewhere. Intensity measurement receives little attention apart from the usual guidance in evaluating errors in counter methods.

More than half of Part 1 concerns various ways of indexing powder patterns. In common with the remainder of the book there are short explanatory sections followed by the relevant data; in the present instance, tables of the necessary trigonometric functions, *d.* v. $1/d^2$, quadratic forms, space group data, Cernohorsky's nomograms, and Hull–Davey and other charts. There are also theoretical line-patterns for some structure types, but these are inferior to those in Part 2 to which, unfortunately, there appears to be no cross-reference. Indexing in the monoclinic and triclinic systems is limited almost exclusively to the use of homology, with only brief mention of, for example, reciprocal-lattice methods: as in other sections, one is reminded that the contents are essentially pre-1961.

Part 1 concludes with standard data and aids required for the calculation of intensities and includes atomic co-ordinates for a number of structure types, and structure factors for a selection of space groups.

Inorganic 'phase analysis' forms a major topic of the second part, and includes Sagel's list (1958) giving structure type and cell dimensions for 1,200 inorganic sub-

stances. The original Russian text also included 126 pages of data from the *A.S.T.M. Powder Data File* (c. 1957) but very sensibly these have been omitted from the present English edition because more accurate and extensive data have become available from the American Society for Testing Materials and also because continuance of the *File* depends on its separate publication. For the cubic, tetragonal and hexagonal systems, however, there are Frevel's theoretical line-patterns for recognizing and indexing many structure types, with tables for identifying some hundreds of compounds in terms of structure type and cell dimensions. Tables of 'homologous pairs' for some two-phase mixtures, and others for the general conversion from weight per cent to atomic per cent, would, like so many of the entries, become useful if one knew they were there.

Precision measurement of lattice constants is another topic receiving special attention with tables of $\frac{1}{2}\lambda\sqrt{N}$, refraction corrections, charts for selection of most suitable wave-length, and description of the classical aspects such as extrapolation procedures and use of least squares. The relatively recent refinements in this field were, of course, only just appearing in the literature at the time of the original publication but, even so, brief mention is made and some references are given.

Three chapters are concerned with extra-structural features such as stress, crystal size, lattice distortion, preferred orientation. To aid stress measurement in iron, copper, aluminium and their alloys, for example, there are Zhmudski's tables (1953) for determining cell dimensions directly from the Bragg angles of certain high-angle reflexions. Investigation of crystallite size, lattice imperfections and lattice distortion are dealt with collectively and there are useful data for profile analysis. Chapters on diffuse and small-angle scattering and on the determination of preferred orientation complete the coverage of X-ray techniques, and the book concludes with short summaries on electron and neutron diffraction.

Dr. Mirkin's compilation, of necessity, overlaps the coverage for the *International Tables for Crystallography* and other established sources, but then extends to give a unique collection of data for the analysis of polycrystalline materials. Where it has drawn, for example, on the *International Tables* one will continue to use the original (which, in some instances, probably contain more complete or up-to-date data). It is for the compilation in English of material from Russian and other sources (notably Sagel's *Tabellen zur Roentgenstrukturanalyse*) not otherwise available in English that the book is so obviously of particular value. Furthermore, some of the tables are here published for the first time or have been expanded for this edition. Unfortunately there are a number of inconsistencies in the book and also a lack of critical assessment which could mislead the inexperienced user.

While easing the retrieval of data from scattered sources this book does, between its own covers, pose a problem in retrieval—especially of the less conspicuous items. The subject index is totally inadequate and there is no author index—the 464 references being listed only by number.

E. G. Steward

RESEARCH IN LEUKAEMIA

Current Research in Leukaemia

Edited by F. G. J. Hayhoe. Pp. xii + 306. (Cambridge : At the University Press, 1965.) 120*s*.

THIS book contains all but four of the papers delivered at a postgraduate medical course in Cambridge in August 1964 by workers mainly drawn from England and Italy, with a few from France, the United States, the U.S.S.R. and Germany.

In the first section of four papers, Merker considers the alkaline phosphatase score, the chromosomes, and neutrophil migration, particularly in chronic granulocytic leukaemia. The phagocytic studies in myeloid forms of leukaemia reported by Marmont and Damasio are interesting but restricted by inadequate quantitative methods. The excellent report by Dmochowski on electron microscopy applied to the viral and mycoplasma aetiology of human and animal leukaemia is unhappily marred by an incorrect order of the 75 clear, well-chosen photomicrographs (this is being corrected in later printings). Harris gives a sound outline of virological studies in avian and murine leukaemia and advises caution in attempting extrapolation to man.

Of the three reports dealing with cytogenetic investigations in leukaemia, that by Hayhoe and Hammouda is the most valuable; it correlates chromosome aberrations with clinical and cytochemical findings in leukaemia and other haematological malignancies. Tough compares the cytogenetics of chronic myeloid leukaemia with and without a significant radiation history, but there are few cases in the former group.

The eight articles in the third and longest section on cell growth and division indicate the recent exuberance of interest in this basic field. Hale and Cooper used autoradiography to investigate the DNA replication of leukaemia cells; Storti and Torelli speculate on differing metabolic types of RNA and its relation to protein synthesis, and Gavosto *et al.* used autoradiography to study DNA synthesis in the chromosomes, extra-chromosomes, and at different times in the *S*-period of mitosis in acute leukaemia.

In the papers dealing with *in vitro* culture systems and phytohaemagglutinin stimulation of leukaemic leucocytes, the metabolic correlations obtained by Quaglino and Hayhoe using autoradiographic and cytochemical methods, combined with the assessment of proliferative capacity by Astaldi *et al.*, form two valuable and complementary contributions. Elves discusses the transformation of lymphocytes to blasts and macrophages, and speculates on haematopoiesis, a subject discussed later by Loutit.

In the longest paper in this symposium, on biochemical aspects of leukaemic cells, Seitz reviews much work on nucleic acid and glycogen metabolism carried out in his laboratory, and published only in the Russian literature. Salvidio and Baldini suggest mechanisms for the differing patterns of enzyme-levels in lyophilized spleens in a variety of conditions. The 'therapeutic experiment' of allogeneic marrow grafting for the treatment of acute leukaemia in animals and man is discussed by Mathé and Amiel.

The final section relates to epidemiological aspects of leukaemia: it includes investigations of the 'summer peak' by Lee and Gardner; on the 'clustering' of cases by Knox; and on incidence and distribution of leukaemia by Doll.

The editor, contributors and publishers are to be congratulated on the speedy production of this volume, which can be recommended to those wishing to have up-to-date reviews in the different fields of leukaemia research. References and the index are good, but throughout one feels the absence of discussion despite the explanation on the cover.

R. Penny

ADHESION AND ADHESIVES

Adhesion and Adhesives

Edited by Dr. R. Houwink and Dr. G. Salomon. Vol. 1: Adhesives. Second, completely revised edition. Pp. xvi + 548. (Amsterdam, London and New York: Elsevier Publishing Company, 1965.) 135*s*.

IT is fourteen years since N. A. de Bruyne and R. Houwink produced the first edition of *Adhesion and Adhesives*, and it would, therefore, seem an appropriate moment for publication of a second enlarged edition in view of the tremendous developments which have occurred

in this period. Full appreciation of the present volume will await the publication of the complementary volume and will be tempered by the emergence over the years of a number of books on the same topics.

The general arrangement of the book is similar to that of the first edition with articles contributed by a team of American, British and Dutch authors, this time largely under the direction of G. Salomon, who writes the first chapter on 'Adhesion'. The subject-matter of this chapter ranges far and wide in order to provide a comprehensive survey of many aspects of adhesive and appropriate polymer science and, consequently, certain areas suffer a somewhat sketchy treatment. However, the subject-matter is well supported by a classified system of 296 references with a brief critique of a number of the more recent books on various aspects of adhesives and adhesion. The succeeding chapters concern themselves with specific classes of adhesives and contain a varying but minor emphasis on adhesion, leaving the subject of applications to Volume 2. Chapters on animal glue and related protein adhesives (A. M. Kragh and J. Wootton) and vegetable adhesives (K. W. Kirby) are followed by a long chapter on synthetic organic adhesives (C. A. A. Rayner), and the length of this and the first chapter, which together comprise more than half of Volume 1, reflect the enormous interest in these fields over recent years. Not only are the important adhesives in the class discussed and an account given of two-polymer adhesives, but again there is a monumental and classified system of references. Chapters on bituminous binders and coatings (R. N. J. Saal) and rubbers (W. C. Wake), the latter including a section on tack, complete the field of organic adhesives. The remaining chapters are on glass, enamels and ceramics (W. van der Colk), inorganic adhesives and cements (J. H. Wills) and, finally, metallic adhesives (W. R. Lewis), including welding.

The overall presentation of the volume is good, and textual errors appear to be few. It supersedes the first edition in that, with the exception of the final chapter, the majority of references given are post-1951. Some readers might have welcomed more chemical formulae in chapters outside their own experience and it seems a pity that, in a book which will no doubt be regarded as both reference and text-book, no author index is provided. All in all, although the present book will not stand out as much as its predecessor in view of other publications on the same subjects, nevertheless it is to be recommended to all interested in adhesion and adhesives, and I for one await publication of the second volume with interest.

R. P. Sheldon

PEASANT FARMING SYSTEMS IN AFRICA

The African Husbandman

By William Allan. Pp. xii + 505 + 7 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1965.) 63*s*. net.

At the present stage of agricultural development in Africa, William Allan could scarcely have written a more basic and pertinent book. African Governments, with the tremendous demands made on them by development, are turning to their countries' agricultural resources for a greater contribution to the economy. They are faced with an enormous proportion of their people dependent on subsistence farming, and increasing population pressures on the land which will rapidly reduce its productivity. It is a vital first step to assess the carrying capacity of land, to give not only a basis for the control of exploitation under existing systems, but also an indication of the potential of the land with regard to improved farming schemes.

Allan set out to measure the carrying capacity of the land, which he terms the "critical population density". He has calculated the critical population density for African peasant systems on the basis of his work and experience with the subsistence cultivators of Northern Rhodesia, now Zambia.

In Part 1 he discusses in detail how the formula for estimating critical population density is built up. He describes the method of classifying the land on an ecological basis, and shows how this relates to the systems of land use practised. He then calculates the critical population density, which is the maximum density that is consistent with the maintenance of the agricultural system without degeneration of the land. Allan describes the different cultivation practices of Northern Rhodesia, and shows how critical population densities were worked out and applied to these systems. This is a very important section and could well be regarded as a working paper for anyone involved in rural development in Africa.

In Part 2 the traditional farming systems of people in other parts of intertropical Africa are described. This section shows that the methods are still valid in widely varying conditions, and gives a basis for their more detailed use.

Perhaps some of Part 3, in the long chapter given over to hunters and food gatherers, could have been condensed, to make room for a more detailed treatment of the weight of information in Part 1. Part 3 also describes the pastoral systems and the relevance of population density estimates to this very significant section of African agriculture.

The final part of the book looks at the effect of change on the African farmer, the factors that have upset the balance of traditional systems, such as the introduction of cash crops, the imposition of peace, and improvement in health of both men and animals. Often the result is a higher standard of living for some, and increased population pressure and its accompanying problems for most. Change goes on, and Allan discusses the attempts being made to adopt systems of improved farming, and the demands that will be made on African agriculture by nations striving for economic development.

The African Husbandman is well written, with occasional delightful touches, such as the author's account (on p. 151) of the 'lawn' of Salvinia on Lake Kariba and the three kudu swimming out of it. He gives the impression of a man who was fascinated and excited with his work, who was also constructive and acute. The text is well documented, with a comprehensive bibliography, but for areas with which one is not familiar it would have been of considerable help to have more sketch-maps; that of Uganda is not particularly accurate.

It is worth noting that the work from which this book emerges was carried out by a team of four: Allan, the agriculturalist; M. Gluckman, the anthropologist; C. G. Trapnell, the ecologist; and D. U. Peters. This brings out the very significant contribution of Allan himself, his ability to view African agriculture in all its aspects, biological as well as economic, and, particularly, social. It is this which gives *The African Husbandman* its authority. Peasant farming systems in Africa are intricately bound up with the social customs and the way of life of the people. Any influence which brings change to the farming system will affect the social structure, and, further, any designs for improved farming are likely to be affected by long-established customs resistant to change. The developing countries are fortunate to have at their disposal a book which has consistently taken these factors into account.

The African Husbandman is a book to be used. Gluckman in his foreword, written from the anthropologist's point of view, says: "I dare affirm that it is equally essential to agricultural scientists". It is indeed equally essential. An agriculturalist would merely have said the reverse, that it was equally essential to the anthropologist. It is to be hoped that it will appear under both subjects in bookshops and catalogues.

H. L. Hutchinson

An Introduction to the Theory of Relativity

By Dr. W. G. V. Rosser. Pp. xiv + 516. (London: Butterworth and Co. (Publishers), Ltd , 1964.) 75*s*.

IN the past, books on special relativity have fallen into two distinct groups. There are some meant primarily for mathematicians which are exhaustive discussions in which the experiments take a back seat and the more abstract parts of the theory are fully developed. Now that the special theory is so well established, there is an important part for such books to play. The fact remains that undergraduates reading physics are not well catered for by these books, and those treatments of the subject which are more slanted towards physicists are all small light-weight accounts. Accordingly, *An Introduction to the Theory of Relativity* meets an important need and it does so magnificently. There can seldom have been such a complete justification for special relativity in terms of experimental results. Every important confirmation of the theory is fully dealt with and discussed in a simple and enlightening way.

The book begins with two chapters of historical introduction, one dealing with mechanics and one with the theories of the ether. The Lorentz transformations are then introduced on the basis of a constant velocity of light, and in the next two chapters their consequences in optics and mechanics are fully discussed. The author then goes over to the use of a four-dimensional representation and uses this to begin his discussion of electromagnetism, starting with the formula for a force between currents. After a fairly conventional treatment of Maxwell's equations, the author devotes a whole chapter to the clock paradox and criticism of special relativity. A concluding chapter gives an intuitive account of general relativity without going into the whole mathematical theory. There is an excellent bibliography and a very full index.

C. W. KILMISTER

Guide to Activation Analysis

Edited by William S. Lyon, Jun. Pp. xix + 186. (Princeton, N.J., and London: D. Van Nostrand Company, 1964.) 46*s*. 6*d*.

GUIDE to Activation Analysis describes the major aspects of activation analysis in eight chapters by different authors: two appendixes give calculated sensitivities and safety and licensing requirements. The first two chapters deal with basic nuclear properties and with reactor neutron flux characteristics, non-reactor neutron sources are then described and compared, and there is a short chapter on the subject of radiochemical separations. Various aspects of counting are considered in two further chapters, less widely applied techniques such as charged particle and γ-photon activation are then described by the Editor himself, and the final chapter is devoted to practical examples of activation analysis.

At a time when intact methods of analysis are becoming more widely applied, the chapter on scintillation counting techniques provides a useful introduction to instrumental methods, and the short section on semiconductor particle detectors is also most topical. It is unfortunate, however, that radiochemical separations, still a very important part of activation analysis, are not more fully discussed.

Valuable information is included in the second chapter on the measurement and application of epithermal and fast reactor neutron fluxes, and Appendix 1 contains a comprehensive bibliography of determinations carried out by activation analysis.

This is a useful book and when used in conjunction with the references quoted it will enable those interested in applying activation analysis to gain a satisfactory basis for their work.

T. B PIERCE

Matrices

Their Meaning and Manipulation. By Prof. W. G. Bickley and R. S. H. G. Thompson. (General Engineering Series.) Pp. xiii + 168. (London: The English Universities Press, Ltd., 1964.) 21*s*. net.

THIS book shows clearly how to present a difficult topic in a concise and interesting manner. The authors have used their great didactic skill in securing the co-operation of the reader, not only by appealing to his sense of purpose, but also by encouraging him to solve numerous problems which supplement the text.

Few would disagree that modern engineers ought to have a rudimentary knowledge of matrices. It is encouraging to see a text which strikes just the right balance between theory and application, includes numerical examples and gives a discussion of pitfalls awaiting the unwary. The book, appropriately enough, starts with a brief description of numerous present-day applications of matrices, both in engineering and in physics. This is followed by a brief exposition of matrix notation, matrix multiplication and its applications, and an introduction to the theory of determinants. The four final chapters cover linear equations (reciprocal matrices), eigen-values and eigen-vectors and a discussion of computational techniques appropriate to both topics. (Here the difficulties of presentation are by no means inconsiderable and it is very much to the credit of the authors that they managed to overcome them so successfully.)

The book, which can be recommended unreservedly as a basis of an excellent introductory course for third-year and postgraduate students, is well produced and very reasonable in price.

P. A. LINDSAY

Comparative Physiology and Pathology of the Skin

Edited by A. J. Rook and G. S. Walton. Pp. xiv + 794. (Oxford : Blackwell Scientific Publications, 1965.) 155*s*.

IT is all too easy for the physician to forget that species other than *Homo sapiens* contribute much more to medicine than their role as experimental animals for drug testing and similar procedures. Other species have their own physiology and pathological disorders, from which a very great deal of information of value to the study of human disease can be learnt, and this is as true of the skin as it is of other organs.

Schwartzman and Orkin's book, *Skin Diseases of Dog and Man*, has aroused a lot of interest since it was published in 1962, and now Rook and Walton have edited an excellent volume, *Comparative Physiology and Pathology of the Skin*, incorporating the proceedings of a symposium held in Cambridge in April 1964.

The contributors include a wide range of veterinarians, biologists, dermatologists and other scientists. The book is divided into sections dealing with comparative dermatology, hair, nutritional influences, porphyria and light sensitization, the mast cell, immunology and tumours of the skin.

The standard of the contributions in the various chapters is almost always quite outstandingly high; as indeed one might expect from the very distinguished contributors. Each appears to have given of his best. Individual readers will naturally find particular sections of special interest to themselves.

Of great merit is the style in which the text is written, a tribute to the authors and editors. It is entirely intelligible to the average reader not working in the specialized field, and so provides a good guide to the interests of other workers.

I find it impossible to give other than the highest praise to the contributors and editors of this book and to the School of Clinical Research and Postgraduate Medical Teaching, and to the Veterinary Medical School of the University of Cambridge who were responsible for arranging the symposium.

C D. CALNAN

ANTHROPOLOGY: ITS ACHIEVEMENTS AND FUTURE*

By Prof. CLAUDE LEVI-STRAUSS
Director of the Institut d'Ethnologie, University of Paris

AMONG the many cherished recollections that I have retained of the years I spent in the United States, one remains outstanding because it is associated with what, due to my inexperience, appeared to me as something of a discovery. Indeed, it embodies for me to this day the unfathomable wealth and mystery of the city of New York.

This apparent discovery took place quite casually one day on lower Broadway, when I stumbled on a bookstore which specialized in second-hand government publications and where could be bought, for two or three dollars apiece, most of the *Annual Reports of the Bureau of American Ethnology*.

I can scarcely describe my emotion at this find. That these sacrosanct volumes, in their original green and gold bindings, representing most of what will remain known about the American Indian, could actually be bought and privately owned was something I had never dreamed of. To my mind, they belonged rather to the same irredeemable past as the beliefs and customs of which they spoke. It was as though the civilization of the American Indian had suddenly come alive through the physical contact that these contemporary books established between me and their time. I felt somewhat akin to a sixteenth-century scholar who, finding in what must have corresponded to our second-hand bookstores old manuscript copies of the works of Homer, Plato or Virgil, is struck by the evidence that these great men had actually existed, since someone had seen and transcribed their written word. Although my financial resources were more than scant and three dollars represented all I had to spend on food for the same number of days, this sum seemed negligible when it could pay for one of these marvellous publications, more alluring to the eye than any costly art books, such as Mallery's *Pictographs*, Matthews's *Mountain Chant*, Fewkes's *Hopi Katcinas*, or such treasure troves of knowledge as Stevenson's *Zuni Indians*, Boas's *Tsimshian Mythology*, Roth's *Guiana Indians*, and Curtin and Hewitt's *Seneca Legends*.

Thus, it happened that, volume after volume, and at the cost of some privations, I built up an almost complete set (there is still one volume missing) of the *Annual Reports* 1–48, which belong to the 'great period' of the Bureau of American Ethnology. At that time, I was far from imagining that, a few months later, I would be invited by the Bureau to become a contributor to one of its major undertakings: the seven-volume *Handbook of South American Indians*.

Notwithstanding this close association and the years which have since elapsed, the work of the Bureau of American Ethnology has lost for me none of its glamour, and I still feel toward it an admiration and respect which are shared by innumerable scholars the world over. Since it so happens that, in the same year that marks the two-hundredth anniversary of James Smithson, the life of the Bureau has come to an end (though its activities are carried on under a new guise), the time may be fitting to pay tribute both to the memory of the founder of the Smithsonian Institution and to the Bureau which has been one of its greatest achievements and certainly a unique one of its kind.

Ever since it was founded in 1879 (which, incidentally, meant the emancipation of ethnology from geography and geology wherewith it had been merged so far), not only did the Bureau avail itself fully of the amazing opportunity provided by the presence of scores of native tribes at a few hours' or days' travel from the great cities, but also, as a distinguished anthropologist Dr. Godfrey Lienhardt puts it in a recent book: "The accounts of custom and culture published by the Bureau compare in thoroughness and quality of reporting with modern ethnographic studies" (*Social Anthropology*, 24, Oxford University Press, 1964). We are thus primarily indebted to the Bureau for instituting standards of scholarship that still guide us, even though we but rarely succeed in attaining them.

Above all, the collection of native texts and factual observations contained in the 48 major *Reports* and certain of the subsequent ones, in the 200 or so *Bulletins* and in the *Miscellaneous Publications*, is so impressive that, despite the use they have been put to for nearly a century, it is safe to say that only the surface has been scratched. This being the case, one can only wonder at the neglect in which this invaluable material has temporarily fallen; as if the far less rich material with which we must content ourselves concerning the beliefs and customs of Greece and Rome were not still laden with as yet unexploited and occasionally unnoted data. The day will come when the last primitive culture will have disappeared from the Earth, compelling us to realize only too late that the fundamentals of mankind are irretrievably lost. Then, and for centuries to come, as happened in the case of our own ancestral civilizations, hosts of scholars will devote themselves to reading, analysing and commenting on the publications of the Bureau of American Ethnology which preserve so much more than has been preserved of other bygone cultures (not to mention the unpublished manuscripts placed in the Bureau's custody): and, if ever we succeed in enlarging our narrow-minded humanism to make it include each and every expression of human nature, thereby perhaps ensuring to mankind a more harmonious future, it is to undertakings such as those of the Bureau of American Ethnology that we shall owe it. However, nothing could be farther from my mind than the notion that the work of the Bureau belongs to the past; I believe, on the contrary, that all of us, together with its legal successor the Office of Anthropology, should seek in these achievements a living inspiration for the scientific task ahead of us.

It has become the fashion in certain circles to speak of anthropology as a science on the wane, on account of the rapid disappearance of its traditional subject-matter: the so-called primitives. Or else it is claimed that, in order to survive, anthropology should abandon fundamental research and become an applied science, dealing with the problems of developing countries and pathological aspects of our own society. I should not want to minimize the obvious interest of these new researches; but I feel, nevertheless, that there is, and will remain for a long time to come, much to be done along the more traditional lines. It is precisely because the so-called primitive peoples are becoming extinct that now, more than ever, their study should be given absolute priority.

It is not too late for hundreds of anthropologists to set to work. As early as 1908, almost sixty years ago, Sir James Frazer, in his inaugural lecture in the University of Liverpool, stated that classical anthropology was nearing its end. What have we witnessed instead? Two great Wars, together with scientific development, have shaken the world and destroyed physically or morally a great many native cultures. But this process, however disastrous, has not been entirely one way. The First World War gave rise indirectly to Malinowski's new anthropology

* Substance of an address delivered in Washington at the Bicentennial Celebration held during September 16–18 commemorating the birth of James Smithson (see *Nature* of October 23, p. 321).

by obliging him to share the life of the Trobriand Islanders in a more durable and intimate manner than perhaps he would have done otherwise. As a consequence of the Second World War, anthropologists were given access to a new world: the New Guinea highlands, with a population of 600,000–800,000 souls whose specific institutions are changing presently our traditional outlook on many theoretical problems. Likewise, the establishment of the new federal capital of Brazil, the building of roads and aerodromes in remote parts of South America, have led to the discovery of small tribes in areas where no native life was thought to exist.

Of course, these opportunities will be the last, and there is no future ahead. Moreover, the compensation they afford is small indeed, compared with the high rate of extinction afflicting primitive tribes the world over. There are about 40,000 natives left in Australia as opposed to 250,000 at the beginning of the nineteenth century, most, if not all, of them hunger-stricken and disease-ridden, threatened in their deserts by mining plants, atom bomb test grounds and missile ranges. Between 1900 and 1950, more than 90 tribes have been wiped out in Brazil, where instead of a hundred there are now barely 30 still living in a state of relative isolation. During the same period, 15 South American languages have ceased to be spoken. Scores of similar examples could be given.

Yet, this is no reason to become discouraged. It is undoubtedly true that we have less and less material to work with. But progress in the meantime, we are able to compensate to some extent for this diminishing volume by putting it to better use, thanks to our greater theoretical and factual knowledge and more refined techniques of observation. If I may put it that way, we have not much left to work with, but we will manage to 'make it last'. We have learned how to look for the cultural 'niches' in which traditional lore finds refuge and where it offers the strongest resistance to the impact of civilization: language, kinship, ethnobotany, ethno-zoology and the like.

But although the physical disappearances of populations that remained faithful until the very end to their traditional way of life does, indeed, constitute a threat to anthropology, curiously enough a more immediate one comes from an evolution which has been taking place in such parts of the world as Asia, Africa and the American Andes, which used to be considered as falling also within the realm of anthropological studies. The demography of these regions was always high and it shows no sign of decreasing; quite the contrary. Physically speaking, the subject-matter is still there, as rich as ever, if not richer still. This new threat to our investigations is not then so much of a quantitative as of a qualitative nature, and this proves to be doubly true: in the first place, these large populations are changing fast, and their culture is resembling more and more that of the Western World. Like the latter, it tends to fall outside the field of anthropology. But this is not all, for the mere fact of being subjected to ethnographical investigation seems distasteful to these peoples, as though by studying the ways in which their old beliefs and customs differed from our own, we were granting these differences an absolute status and conferring on them a more enduring quality.

Contemporary anthropology thus finds itself in a paradoxical situation. For it is out of a deep feeling of respect toward cultures other than our own that the doctrine of cultural relativism was evolved; and it now appears that this doctrine is deemed unacceptable by the very people on whose behalf it was upheld, while those ethnologists who favour unilinear evolutionism find unexpected support from peoples who desire nothing more than to share in the benefits of industrialization, and prefer to look at themselves as temporarily backward rather than permanently different.

Hence the distrust in which traditional anthropology is held nowadays in some parts of Africa and Asia. Economists and sociologists are welcome, while anthropologists are tolerated at best, and from certain areas they are simply banned. Why perpetuate even in writing old usages and customs which are doomed to die? The less consideration and attention they receive, the faster they will disappear: and even should they not disappear, it is better not to mention them lest the outside world realize that one's culture is not as fully abreast with modern civilization as one deludes oneself in believing it to be. There have been periods in our own history when we too have yielded to the same delusion, only to find ourselves struggling to regain balance after eradicating so recklessly the roots that held us back to our past. Let us hope that this dire lesson will not be lost on others. The question is, in effect: what can we do to keep it from being lost? Is there a way of making people realize that they have a tremendous responsibility toward themselves and toward mankind as a whole, which is not to let perish before it has been fully recorded this past it is their unprecedented privilege to experience on a par with their incipient future? The suggestion has been made that in order to render anthropology less distasteful to its former human raw material, it will suffice to reverse the roles and occasionally allow ourselves to be 'ethnographized' by those for whom we were once solely the ethnographers. In this way, each in turn will get the upper hand. Since there will be no permanent privilege, nobody will have grounds to feel inferior to anybody else. At the same time, we shall get to know more about ourselves through the eyes of others, and human knowledge in general will derive an ever-growing profit from this reciprocity of perspective.

Well meant as it undoubtedly is, this solution appears naïve and unworkable to this speaker; as though the problems involved in the great confrontation now taking place between Western culture and the rest of the world were as simple and superficial as those of children unaccustomed to play together, whose quarrels can be settled by making them follow the elementary rule: "Let me play with your dolls and I shall let you play with mine". To arrive at an understanding between people who are not merely estranged from one another by their physical appearances and their peculiar ways of life but who also stand on an unequal footing to one another, is a different question altogether.

Anthropology is not a dispassionate science like astronomy, which springs from the contemplation of things at a distance. It is the outcome of a historical process which has made the larger part of mankind subservient to the other, and during which millions of innocent human beings have had their resources plundered, their institutions and beliefs destroyed, while they, themselves, were ruthlessly killed, thrown into bondage and contaminated by diseases they were unable to resist. Anthropology is daughter to this era of violence: its capacity to assess more objectively the facts pertaining to the human condition reflects, on the epistemological level, a state of affairs in which one part of mankind treated the other as an object.

A situation of this kind cannot be soon forgotten, even less erased. It is not on account of its mental endowments that only the Western world has given birth to anthropology, but rather as a consequence of the fact that exotic cultures, treated by us as mere things, could be studied, accordingly, as things. We did not feel concerned by them, whereas we cannot help their feeling concerned by us. Between our attitude toward them and their attitude toward us, there is and can be no parity.

Therefore, if native cultures are even to look at anthropology as a legitimate pursuit, and not as a sequel to the colonial era or that of economic domination, it cannot suffice for the players to simply change camps while the anthropological game remains the same. Anthropology itself must undergo a deep transformation in order to carry on its work among those cultures for the study of which it was intended because they lacked a written record of their past history. This, however, it will achieve in an

altogether different way, since instead of making up for this gap through the application of special methods, the aim will be to fill it in. Whenever practised by members of the culture which it endeavours to study, anthropology loses its specific nature and becomes rather akin to archaeology, history and philology. For inasmuch as anthropology is the science of culture as seen from the outside, it follows that the first concern of people made aware of their independent existence and of their originality could not be to observe from the outside the culture of their former masters while allowing the latter to observe their own culture also from the outside, but to claim the right to observe this culture of theirs themselves, and in the only way, that is, from the inside. The obvious conclusion is that anthropology will survive in a changing world by allowing itself to perish in order to be born again under a new guise.

Anthropology is thus confronted with two tasks which would prove contradictory only were they to be undertaken simultaneously in the same field. Wherever native cultures, though disappearing physically, have remained to some extent morally intact, anthropological research should be carried out along traditional lines and the means at its disposal increased to the utmost. Wherever the opposite situation prevails, that is, where populations have remained physically strong while their culture is rapidly veering toward our own, anthropology should accept to shift its goals and, while being taken over progressively by scholars from the land, adopt aims and methods similar to those which, from the Renaissance on, have proved fruitful for the study of our own culture.

From the very beginning, the Bureau of American Ethnology has had to face this two-fold necessity by reason of the peculiar situation of the American Indian who allied cultural remoteness and physical proximity, together with a tremendous will to live, at least among some tribes, despite all the ordeals they have been subjected to; thus the Bureau was compelled from the start to act both ways: on one hand, through ethnographical surveys, the precision and rigour of which have set up a standard that cannot be surpassed, and on the other, by encouraging the natives themselves to become their own linguists, philologists and historians. If the cultural riches of Africa, Asia and Oceania are to be saved, it will only be on the condition that, following this example, we succeed in raising dozens (and they themselves hundreds) of such men as Francis La Flesche, son of an Omaha chief, James Murie, a Skidi Pawnee, George Hunt, a Kwakiutl, and many others, some of whom, like La Flesche and Murie, were on the staff of the Bureau.

When we consider that this was taking place more than fifty years ago, we can but marvel at such maturity and foresight, and hope for the extension, on a world scale, of what a handful of resolute and enlightened men and women knew should be done in the wide field of American studies. Indeed, they did it in such an efficient way that through less than a century of effort on their part, a great deal more similar material to that which is already available. There remains such a considerable amount to be saved that the urgency of the task risks making us overlook the present evolution of anthropology, which as it increases in quantity is also changing in quality. Recognition of this fact should make us more confident in the future of our studies, and it can be verified in many ways. To begin with, new problems have arisen which can still be solved, even though they have received but scant attention thus far. It is worth noting, for example, with what disdain until recently anthropologists have neglected to study the relationship, in the case of each crop, between the amount of work involved and the yield, as well as the latter's elasticity. Yet one of the keys to the understanding of the social and religious importance of yams, which is so striking throughout Melanesia, can probably be found in the remarkable elasticity of the yield. The farmer who is exposed to harvesting far less than he actually needs must plant far more in order to be reasonably certain of having enough. Conversely, if the harvest is plentiful it can so widely exceed expectations that to consume it all becomes impossible; this leaves no other use for it than competitive display and social food presentation. In cases such as the foregoing, as in many others, we must learn to translate, in terms of several different codes, phenomena that we have been apprehending so far in terms of one or two codes only, and thus render the observed phenomena a great deal more significant.

A wide system of equivalents could then be established between the truths of anthropology and those of neighbouring sciences which have been progressing at a similar pace: I am thinking not only of economics, but also of biology, demography, sociology, psychology and logics, for it is through a number of such adjustments that the originality of our field will best appear.

There has been much question lately as to whether anthropology belonged among the humanities or among the natural sciences. In my opinion this is a false problem, since anthropology has the unique feature of not lending itself to such a distinction. It has the same subject-matter as history, but for lack of time perspective cannot use the same methods. Its own methods tend rather towards those of sciences not devoted to the study of man, though synchronically oriented like anthropology itself. As in every other scientific undertaking, these methods aim at discovering invariant properties beneath the apparent particularity and diversity of the observed phenomena.

Will this assignment deter anthropology from a humanistic and historical outlook? Quite the opposite is true. Of all the branches of our discipline, physical anthropology is probably the closest to the natural sciences. For this very reason, it is worth noting that, by refining its methods and techniques, it has been getting ever closer to, not farther from, a humanistic outlook.

For the physical anthropologist, to look for invariant properties traditionally meant to look for factors devoid of adaptative value and from the presence or absence of which something could be learned about the racial divisions of mankind. Our colleagues are less and less convinced, though, that any such factors really do exist. The sickle-cell gene, formerly held as one, can no longer be considered in that light if, as is now generally accepted, it carries a certain measure of immunity to malaria. However, as Dr. Frank B. Livingstone has brilliantly demonstrated (*Amer. Anthropologist*, 60, No. 3, 533; 1958), what appears as an irretrievable loss from the point of view of long-range conjectural history can be viewed as a definite gain from that of history as historians conceive it, that is, both concrete and at close range. For by reason of the adaptive value of the sickle-cell gene, a map showing its distribution throughout the African continent would make it possible for us to read, as it were, African history in the making, and the knowledge thus obtained could be correlated with those same invariant properties which have vanished at the superficial level where they were sought for originally, to reappear at a deeper functional level; and whereas they seem to grow less informative, they turn out to be more meaningful.

This remarkable process is actually taking place everywhere in our field. Dr. George M. Foster has recently given new life to what most of us held to be an exhausted question: the origin of the potter's wheel (*Southwestern J. Anthropol.*, 15, No. 2, 99). This he achieved by pointing out that an invention is neither simply a new mechanical device nor a material object that can be described objectively, but rather a manner of proceeding which may avail itself of a number of different devices, some of them crude and others more elaborate. In the field of social organization, I myself have tried to show that kinship systems should not be described by their external features such as the number of terms they use, or the way they classify, merge and distinguish all possible ties between

individuals. In so doing, all we can hope to obtain is a long list of types and sub-types which are there simply as meaningless objects, while if we try to find out how they work, that is, what kind of solidarity they help to establish within the group, their apparent multiplicity finds itself reduced to a few basic and meaningful principles.

Similarly, in the field of religion and mythology, an attempt to reach beyond external features, which can only be described and arbitrarily classified by each scholar according to preconceived ideas, shows that the bewildering diversity of mythical motifs can be reduced to a very few number of schemes, each of which appears endowed with a specific operational value. At the same time there emerge for each culture certain sets of transformation rules which make it possible to include in the same group myths previously held to be markedly different.

These examples, chosen among many others, tend to show that anthropology's traditional problems are assuming new forms while none of them can be said to be exhausted. The distinctive feature of anthropology, and that which singles it out among other human sciences, is to look at man from the very point where, at each period of history, it was considered that anything man-like had ceased to exist. Within a century or so, when the last native culture will have disappeared from the Earth and our only interlocutor will be the electronic computer, it will have become so remote that we may well doubt whether the same kind of approach will deserve to be called 'anthropology' any longer. Between these limits lies the only chance that man ever had or will have to look at himself in the flesh while still remaining a problem unto himself, though one he knows can be solved since it is already certain that the outer differences conceal a basic unity.

Let us suppose for a moment that astronomers should warn us that an unknown planet was nearing the Earth and would remain for twenty or thirty years at close range, afterwards to disappear for ever. In order to avail ourselves of this unique opportunity, neither effort nor money would be spared to build telescopes and satellites especially designed for the purpose. Should not the same be done at a time when one-half of mankind, only recently acknowledged as such, is still so near to the other half that except for men and money its study raises no problem, although it will soon become impossible for ever? If the future of anthropology could be seen in this light, no investigation would appear more urgent and no other could compete with it in importance. For native cultures are disintegrating faster than radioactive bodies, and the Moon, Mars and Venus will still be at the same distance from the Earth when that mirror which other civilizations still hold up to us will have so receded from our eyes that however costly and elaborate the instruments at our disposal we may never again be able to recognize and study this image of ourselves which will be lost and gone for ever.

ORIGIN OF PRECIOUS OPAL

By P. J. DARRAGH, A. J. GASKIN and B. C. TERRELL
C.S.I.R.O. Division of Applied Mineralogy, Melbourne
AND
DR. J. V. SANDERS
C.S.I.R.O. Division of Tribophysics, Melbourne

ELECTRON microscopy has shown[1] that the play of colours or 'fire' in precious opal is caused by diffraction effects from arrays of uniformly sized spheres of amorphous silica 1700–3500 Å in diameter. The spacing of the regular optical discontinuities in the arrays is determined by the diameter of the spheres and in turn determines the maximum wave-length which can be diffracted. With this relationship in mind we have examined many opal specimens from museums and private collections, studied the occurrence of the mineral in some Australian fields and synthesized opaline silica in the laboratory. We have reached certain tentative conclusions concerning the origin of precious opal and consider that some of these may be relevant in principle to the genesis of all opaline silica.

We find that the spheres in precious opal, and the common opal or the 'potch' with which it is associated, have an internal structure which suggests to us that these particles are secondary colloidal aggregates of primary particles up to 400 Å in diameter. We consider that the primary particles formed in ground-water which became concentrated by evaporation in partly filled cavities at shallow levels. Water evaporated from the free surfaces of liquid in the cavities at a rate limited by the vapour pressure gradient or the permeability of the cover rock, but the surfaces were kept at constant level by inflow of more solution from adjacent ground-water traps. The concentration of silica increased and, as primary particles formed, the contents of the cavities became thin gels. With increasing concentration, secondary aggregates developed to a critical size and settled through the gel, the consistency of the gel thus determining the maximum particle size. If the secondary particles were well-formed spheres and settled at an appropriate size, uniform close-packed arrays capable of diffracting visible light were generated and the material could become precious opal. If the rigidity of the parent medium prevented secondary particle growth, or inhibited the formation of regular spheres, or impeded selective settling of the larger particles only common opal or potch could be formed. In the final stage of cementation, desiccation of the environment caused the soft spheres and arrays to harden by loss of water and deposition of further silica. The quality of the 'fire' exhibited by the stone is influenced by the extent to which interstitial voids remained unfilled.

Field Environment of Opal

The main opal fields of Australia are situated in arid inland regions where the mineral occurs in a sub-horizontal sequence of Cretaceous claystones and thin bentonite beds. The claystones are composed of fine angular quartz and coarse kaolinite and are highly permeable. Siliceous duricrust up to 3 m in thickness covers much of these and is apparently of late Tertiary age[2]. Opal is found from depths as great as 60 m up to the surface, where it has been exposed by post-Tertiary erosion. We estimate that opal has been deposited under a cover of 5–40 m of rock during the Tertiary period, under climatic conditions not greatly different from those prevailing at present.

We consider that three features of the Australian fields have been particularly significant in the genesis of the opal.

(1) An abundant supply of readily soluble silica has existed in the host sediments. Detrital feldspars have been kaolinized *in situ* in the claystones, liberating silica in solution. Diagenetic changes associated with the benton-

ites could also have produced silica of the opaline variety giving the 'cristobalite' X-ray pattern known to be characteristic of such clays[3]. Amorphous silica micro-fossils and volcanic ash fragments have been recorded in some of the beds[4].

(2) The aridity of the climate has restricted the shallow ground-waters of the opal fields to sharply defined formational dams, such as the bentonite beds, for periods of millions of years. Except in the vicinity of such water traps, the rocks have dried out to depths of many metres. At present, ground-waters may be fresh where part of the drainage system, but where stagnant may contain up to 3 per cent of mixed sulphates and chlorides, 80 p.p.m. of silica and have slightly acid characteristics. Carbonated alkaline artesian waters exist at depths of 700–1,200 m in many fields but the present distribution of these shows no relation to the occurrence of opal.

(3) Opal typically occurs either as a cavity filling in the vicinity of junctions of bentonitic beds with overlying porous rocks or as slabs in joints and solution channels. Cavities have been formed throughout the host rocks by minor deformation and by the removal of fossils and minerals through decomposition or leaching. Many cavities remain unfilled and even within a favourable level the distribution of opal is very patchy. Most cavities along the top of a bentonite band may contain opal over an area of hundreds of square metres but immediately outside this area all similar spaces may be empty. Where cavities in porous rock have been filled with opal the rock pores are usually also filled, generally with opaline silica showing no 'fire' but occasionally with precious opal of the type called 'matrix'. Where masses of opal occur in bentonite the surrounding sediment is generally not silicified. Precious opal does not 'replace' other materials except by filling spaces left by extraction of the original substance. Veins of gypsum and alunite are commonly situated above opal levels along the upper surfaces of bentonite beds and opal may include or be included by these minerals.

Supply and Deposition of Silica

Since the sediments of the Australian opal fields have been rich sources of soluble silica and the amounts of ground-water present have been limited, we consider that water in formational traps could have dissolved up to 100 p.p.m. of silica from the host rocks at 20°–25° C under neutral or slightly acid conditions. Such solutions could have migrated laterally to places where evaporative loss of water through the rock cover concentrated the solutions to the point of deposition of colloidal silica. We have found no evidence to suggest that the solutions responsible for opal deposition were different from present-day ground-waters, and in fact we see no reason why the deposition of opal could not still be continuing in parts of these regions.

All field evidence is consistent with the suggestion that opal has been formed by slow evaporation of very limited and highly localized supplies of ground-water, a process similar in some respects to the formation of surface duricrust but occurring under a protective cover of rock sufficient to isolate the system from seasonal drying and flooding. Opal host cavities have characteristically been those situated in positions permitting steady-state concentration of ground-water by evaporation. Soluble salts have been removed by diffusion to zones, above the cavities, where crystallization occurred as capillary flow ceased. This separation of salts from colloidal silica particles has been an important factor enabling silica to be spatially concentrated in appreciable masses, sufficiently free from physical disruption to achieve the structure required for optical diffraction effects.

For purposes of illustration we may consider the typical situation of an isolated host cavity that has been situated in a wet zone near the top of a bentonite bed under a cover of porous claystone. In this zone capillaries were saturated, but a larger space, such as the host cavity, contained a free water surface. As water vapour left the free surface and migrated up to the atmosphere through the permeable cover rock, small primary colloidal silica particles formed as the residual solutions became concentrated. The level of the free liquid surface in the cavity was maintained by hydrostatic inflow of ground-water from points further along the formational dam. Particles grew to a diameter of 300–400 Å and settled as loose flocs, to give a zone with the consistency of very thin gel on the floor of the cavity. This zone of high population density of primary particles acted as the parent medium for the formation of secondary colloidal aggregates. Primary particles removed in the formation of the aggregates were continuously replaced by fresh particles diffusing down through the thin gel as evaporation proceeded.

It may be seen that the concentrating mechanism in our model is a free water surface from which vapour is progressively removed. Such surfaces may have existed in a host cavity, or in voids connected with the cavity by channels permeable to sol particles. If we consider a model in which the walls of a cavity were permeable only to solutions and assume that a free surface was continuously maintained in the cavity, the rate of deposition of opal may be estimated by calculating the rate at which a 100 p.p.m. silica solution could be concentrated in the cavity. This rate would be controlled either by the permeability of the cover rock to water vapour or the rate at which water could evaporate from the free surface and condense at the roof of the cavity under the influence of the thermal gradient in the surrounding rock. At deep opal levels the thermal gradient could be assumed constant at about 0·05° C per metre, the temperature decreasing towards the base of the zone of seasonal variation. This would give an evaporation flux across the cavity of the order of 10^{-10} g/cm²/sec. From measurements of the permeability of the cover rock at Andamooka we consider that this flux would readily have been sustained, even where thin bands of bentonite occur in the sequence. A spherical cavity losing water at this rate would concentrate silica solution at a rate sufficient to deposit a layer of opal up to 1 cm thick in 5 million years, even at a depth of 40 m. Opal at higher levels could have been deposited more rapidly, especially in cavities covered only by porous claystone, or at places connected with the ground surface through vertical open joints. At a depth of 10 m the maximum rate of deposition possible from a 100 p.p.m. silica solution would have been about 1 cm in 200,000 years, but this implies direct connexion to the atmosphere, an improbable condition in our view.

Rates of opal deposition calculated for an isolated cavity would not apply to a cavity connected to extensive areas of free surfaces in surrounding voids. Sol particles generated in such voids interconnected across an appreciable area of a formational dam could presumably be laterally segregated by fluid flow towards particular cavities which would therefore fill at higher rates. The large slabs of opal in joint systems and solution channels probably formed by this mechanism. Such material is generally potch, the best quality precious opal being found in small isolated cavities where the material has been formed by concentration of solution *in situ*. Opal from isolated cavities may show evidence of discontinuities in deposition, probably caused by periods of raised water level rather than desiccation. The quality of the stone then changes abruptly through a succession of sharply defined horizontal layers, the breaks in deposition being occasionally marked with films of clay. Textural evidence from masses of opal in open joints shows that such cavities have dried out on occasion, the existing opal having been cracked through shrinkage and the cracks filled in with later opal. The time required to cause such desiccation would not have been significant compared with the total time required to deposit the opal, but the observation supports the concept that the climate was arid when the opal was formed.

Development of Spheres

The growth of colloidal silica particles appears to be a complex phenomenon involving condensation reactions and aggregation effects. As solutions concentrate by evaporation macromolecules form by condensation of small polyanions in reactions liberating water. These macromolecules aggregate and become welded together by further condensation reactions to form sol particles, the distinction being made, by definition, when the particle diameter exceeds 10 Å. Particles are spherical because the substance is essentially amorphous and isotropic. Diameters of up to 300–400 Å are readily attained and the sols tend to become rather monodisperse, possibly because the systems are of the type in which particles, growing by the operation of a substantially linear growth-rate law, are being supplied with nutrient at a steady rate[5]. As the particle diameter increases, aggregation becomes the dominant growth mechanism, as small particles formed by condensation reactions become incorporated in the larger spheres before reaching any significant size. This change may be demonstrated by holding a sol for a long period with the nutrient supply cut off. Under such conditions a silica sol of particle size around 100 Å held for some months at room temperature becomes a suspension of secondary spherical aggregates 1500–2000 Å in diameter[6] as long as no flocculating ions are present to form a gel network which can severely impede aggregation. The term 'secondary' is used for convenience but has no absolute connotation in the silica system, where 'primary' particles may have formed by a similar aggregation mechanism on a smaller scale.

Electron micrographs of etched opal surfaces show that the large spheres are secondary aggregates of primary particles 300–400 Å in diameter. Australian opal generally shows the details of the internal structure of such aggregates better than opal that we have examined from other parts of the world. The structure has been found in Hungarian opal, but not in Mexican 'fire opal' nor in the black glassy variety from Nevada. In well-developed secondary aggregates a core is surrounded by 1–3 concentric shells of primary particles, the smaller aggregates having fewer shells (Fig. 1). Opal showing only green-blue-violet 'fire' usually has a sphere structure of 2 shells around a small core, or one shell around a larger core apparently formed by less regular aggregation of primary particles. Opal showing red 'fire' contains spheres larger than 2500 Å in diameter and these may have 3 shells around small cores.

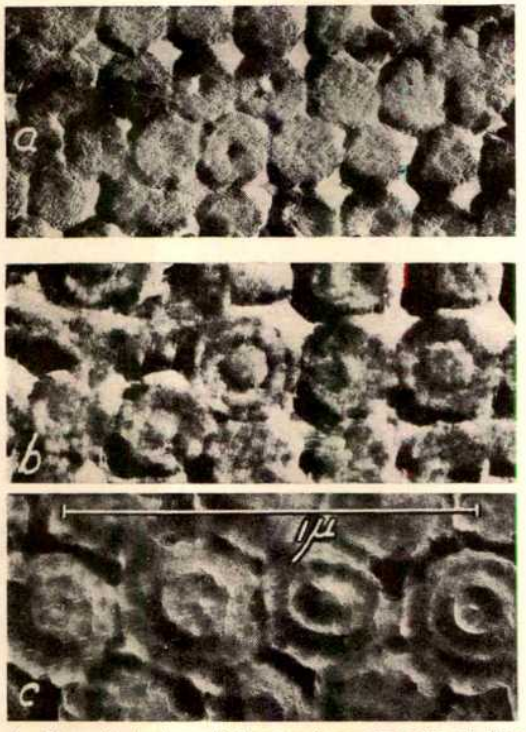

Fig. 1. Internal structure of the secondary aggregates of silica in Australian opals: (*a*) violet, (*b*) green and (*c*) red. Shadowed replica of surfaces etched in hydrofluoric acid (× 55,000)

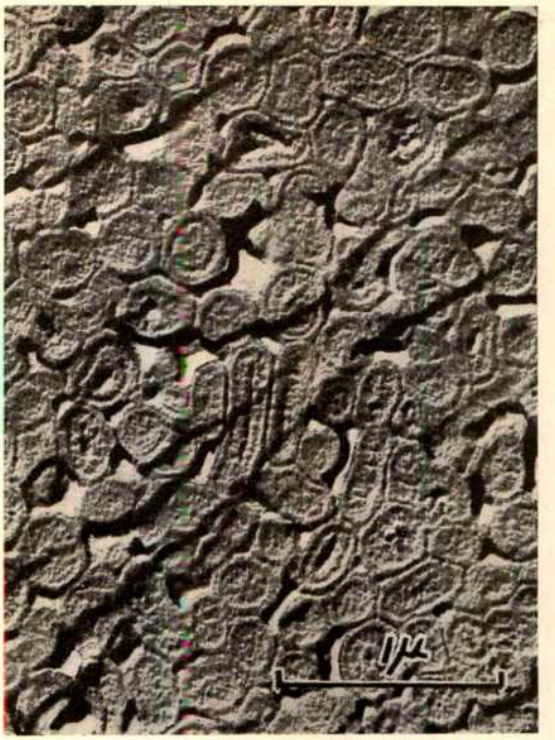

Fig. 2. Distorted cores and particle shapes in 'potch' opal from Andamooka. Shadowed replica of etched surface (× 30,000)

The perfection of shape of secondary aggregates is greatest in precious opal, where regular spheres have been formed and arranged in precise arrays of uniform particle size. In potch, secondary aggregates may be so malformed that arrangement in regular arrays has not taken place. Ellipsoidal aggregates formed around multiple cores, especially around straight chains of core particles, are common (Fig. 2). We consider that the consistency of the gel medium determined the perfection of shape of secondary aggregates. The more perfect spherical clusters probably developed in thin media which allowed greater freedom of movement of primary particles, while potch particles formed in thicker, more concentrated gels which inhibited the development of minimum free energy spherical clusters in the time available. This accords with the presence of the more perfectly shaped particles in opal deposited in small cavities by evaporative concentration of solution within the cavities. Secondary particles in other varieties of natural opaline silica examined to date are less than 1500 Å in diameter and are generally rather irregular in shape. Siliceous duricrust, wood opal, common opal and silica deposited in plants are all materials in this category.

Packing of Spheres

Iler has described the spontaneous formation of diffracting arrays of silica particles 1100 Å in diameter in aqueous suspensions left to stand for long periods[7]. Such small particles should diffract ultra-violet rather than visible wave-lengths and it seems likely that the colours he observed were produced by diffraction effects from irregularities in the arrangement of the spheres. We have grown spheres up to diameters of 2000–6000 Å by modifications of the techniques of Bechtold and Snyder[8], and we find that diffracting arrays may be prepared from these

within an hour by centrifuging. The colours can be preserved to some extent by drying and cementing the sedimented masses.

A special feature of the natural opal system is that spheres have been both formed and arranged in a still medium. This would not be possible in the laboratory systems that we have used, because large secondary particles sink into packed arrays within a few days in media having a viscosity near that of water. Primary particles 300 Å in diameter would not enter close-packed arrays of secondary spheres and aggregates would not continue to grow once settled into such arrays at a diameter of about 1000 Å. We therefore propose that secondary aggregates in opal grew in a gel medium of sufficient consistency to hold the particles suspended for long periods while growth by accretion of primary particles proceeded. When secondary aggregates became large enough to break free of the bonds holding the particles suspended in the gel network, sedimentation occurred, the particles joining regular arrays building up from the floor of the host cavity. In these close-packed arrays further growth of spheres by accretion of primary particles was impossible.

In our view the consistency of the parent gel has therefore determined the size to which spheres have grown. Very thin media allowed early settling of relatively small spheres, producing arrays on the scale characteristic of opal showing only violet 'fire'. Thicker media retained spheres in growth positions until the sizes characteristic of opal with green or red 'fire' were reached. Potch media were occasionally too thick to allow differential settling and the collections of particles that resulted were polydisperse, with a diameter range of 600–4000 Å in a single specimen.

According to our interpretation of the mechanism controlling particle-size distributions in precious opal, there was generally a systematic variation in the consistency of parent media during the deposition of the mineral. Arrays of spheres formed in the shape of vertical pseudo-crystals in most opal and such structures in specimens of known orientation that we have examined generally show a gradual transition in particle size, the spheres decreasing in diameter from the base of a pseudo-crystal to the top. The common gradation in the quality of the 'fire' exhibited is from red at the base to green at the top, suggesting that parent media became thinner as sedimentation of spheres proceeded. This supports the view that the spheres were formed by slow reorganization of the parent gel, the rate of supply of new primary particles being insufficient to maintain a gel network at constant consistency. The transition from larger to smaller spheres up the columnar arrays is not always shown, and we have in fact observed some instances of reversal, especially in thin vertical veins and in 'matrix' opal. In these, red-diffracting particles have been retained in the upper limits of vertical veins, possibly because the parent gels in such positions were drier and of thicker consistency than the media in the main opal levels below.

Macroscopic structures preserved in opal give some indication of the consistency of the parent gels. Loose flocs have been kept in suspension in some samples and the spheres developed in the flocs have been different from those in the surrounding gel. Gels have been unable to support sand-sized rock particles which have become detached from the roof of the host cavity, but flow lines have developed around the falling particles as existing arrays of spheres were disturbed. Such observations suggest that parent media had a consistency similar to that of fresh 0·1 per cent silica sol fully flocculated with salts.

Process of Cementation

When first formed, the secondary spheres in natural or synthetic opaline silica are soft, the component primary particles being held together by relatively weak bonds. Synthetic spheres can be deformed into polyhedra by excessive centrifuging or rapid drying and similar effects caused by compression during packing can be seen in electron micrographs of natural opal. Spheres become harder and denser on drying, especially if a little residual silica is present in the liquid being evaporated. In natural opal, arrays appear to have remained soft and uncemented for long periods before being hardened by desiccation, successive generations of different arrays having been deformed mechanically at the same time while still in a soft condition.

The consolidation of arrays by deposition of further silica and deformation of spheres during drying has given the degree of transparency required for the display of optical diffraction effects in opal, but the quality of the 'fire' is strongly affected by the extent to which the voids between the spheres have been filled. If the spheres were deformed and compressed into complete contact or if almost all the optical discontinuities were eliminated by deposition of interstitial silica, the intensity of the 'fire' is weak, as in jelly opal and Mexican opal. Complete elimination of discontinuities has produced glassy potch. If many irregularly arranged spaces have been left, general scattering of white light dilutes the 'fire', giving a milky variety.

Freshly formed synthetic opal gives a very diffuse X-ray pattern of the cristobalite type shown by precious opal. The pattern sharpens after several months' dehydration at 100° C, suggesting that variations in the patterns of different natural opals[9] may reflect the time and degree of exposure of the mineral to hot, dry conditions. We consider that the natural drying of opal in the Australian fields took place during Quaternary time, as erosion removed part of the rock cover and destroyed the continuity of shallow ground-water systems.

We thank the Australian Museum and the School of Mines, Kalgoorlie, for loans of specimens. We also thank the miners and cutters of Andamooka and Coober Pedy and the opal field wardens of the South Australian Department of Mines for their assistance.

INTERNATIONAL GEOPHYSICAL CALENDAR FOR 1966

THE International Geophysical Calendar for 1966 has been drawn up by A. H. Shapley, chairman, and J. V. Lincoln, deputy secretary, of the Steering Committee of the International Ursigram and World Days Service, in close association with the International Geophysical Committee and the reporters and spokesmen for the various scientific disciplines, International Years of the Quiet Sun and the Committee of Space Research.

The Calendar designates days and intervals selected for special attention for geophysical observations, experiments, data interchange or analyses (Table 1). It is thus a framework for world-wide and interdisciplinary co-ordination in those programmes where it is not practical or meaningful to carry out the same work for each and every day. The Calendar serves mainly the branches of geophysics dealing with the Earth's atmosphere. A principal

use is for the co-ordination of the sampling of the many phenomena which vary significantly during the course of a year. The Calendar is prepared especially for the suggested scientific programmes recommended to be carried out for the days or intervals marked on the Calendar (see paragraphs 11–16). It is also common for individual geophysical stations or groups of stations to arrange some of their plans of observations according to the Calendar. Thus geophysicists can expect that their colleagues in other countries, in other laboratories and in other geophysical disciplines will tend to be making increased efforts for the days and intervals marked on the Calendar; the amount of geophysical data in existence, at the World Data Centres and elsewhere, will accordingly be greater for Calendar days.

(1) *Universal Time* (U.T.) is the standard of time for all world days on the Calendar, that is, each begins at 0000 U.T. and ends at 2400 U.T.

(2) *Regular Geophysical Days* (*RGD*) are each Wednesday throughout the year. This weekly sampling schedule is particularly designed for the purposes of the meteorological programme but has also been adopted for some other geophysical programmes.

(3) *Regular World Days* (*RWD*) are three consecutive days each month, always Tuesday, Wednesday, Thursday near the middle of the month. They are intended for observations, experiments or analyses which can or need be made for about 10 per cent of days and which should be spaced (in groups of three days) throughout the year.

(4) *Priority Regular World Days* (*PRWD*) are one day each month—the *RWD* which are also a *RGD* (Wednesdays). They are for work which can or needs to be done only one day each month throughout the year.

(5) *Quarterly World Days* (*QWD*) are one day in each quarter of the year. They are the *PRWD* which fall within the World Geophysical Intervals (*WGI*) and are also a *RGD* (Wednesday). The *QWD* serve to co-ordinate seasonal high-altitude rocket experiments.

(6) *World Geophysical Intervals* (*WGI*) during 1966 are fourteen consecutive days in each season, beginning on the second Monday of the selected months. They always include the three *RWD* of the month and the *QWD* for the season. The *WGI* are intended for intensified programmes aimed at the statistics of seasonal variations or the timing of seasonal changes. The schedule of *WGI* relative to the equinoxes and solstices is deliberately made different from year to year so that in due course a *WGI* will cover the time of seasonal change of each of various geophysical phenomena; variations from this principle will sometimes be made in order to include a solar eclipse within a *WGI*.

(7) *Solar Eclipses* are May 20 (annular) with central line extending from North Africa to Central Asia, and November 12 (total) with central line extending from the equator west of South America, to a point south of South Africa. Geophysical stations in the eclipse zones treat these days as world days and undertake special programmes to investigate eclipse effects on the Earth's atmosphere. (For maps of the eclipse zones and pertinent details see any standard astronomical ephemeris or yearbook.)

(8) *Meteor Showers* of special interest are also marked on the Calendar, including some of the important visual showers and also unusual showers observable mainly by radio and radar techniques. Attention is directed to these days (selected by P. Millman, Ottawa) in case ionization produced by meteors may account for unusual effects in other geophysical experiments. In 1966 the Leonid meteor shower, Nov. 16–17, may be stronger than in the past 25 years. Although the Leonids gave spectacular displays in 1833 and 1866–67, planetary perturbations prevented a repeat of these displays in 1900 and 1933.

Table 1. World Days marked on the Calendar

1966	*RWD*	*PRWD*	*QWD*	*RGD*	*WGI*	*Ecl.*	Meteors
Jan. 11, 12, 13	12	—	5, 12, 19, 26	—	—	3–4
Feb. 15, 16, 17	16	16	2, 9, 16, 23	7–20	—	—
Mar. 15, 16, 17	16	—	2, 9, 16, 23, 30	—	—	—
Apr. 12, 13, 14	13	—	6, 13, 20, 27	—	—	22
May 17, 18, 19	18	18	4, 11, 18, 25	9–22	20	4–6
June 14, 15, 16	15	—	1, 8, 15, 22, 29	—	—	6–10
July 12, 13, 14	13	—	6, 13, 20, 27	—	—	28–30
Aug. 16, 17, 18	17	17	3, 10, 17, 24, 31	8–21	—	10–14
Sep. 13, 14, 15	14	—	7, 14, 21, 28	—	—	—
Oct. 11, 12, 13	12	—	5, 12, 19, 26	—	—	20–21
Nov. 15, 16, 17	16	16	2, 9, 16, 23, 30	7–20	12	16–17
Dec. 13, 14, 15	14	—	7, 14, 21, 28	—	—	12–14 22–23

(9) *World Days not appearing on Calendar*. The occurrence of unusual solar or geophysical conditions is announced or forecast through various types of geophysical 'alerts' which are widely distributed by telegram and radio broadcast on a current schedule. The types of alerts are: magnetic storm (in telegrams *magstorm*), magnetic calm (*magcalme*), solar flare (*soflare*), solar activity (*solactivity*), cosmic ray event (*cosmic event*), and sudden and unusual stratospheric warmings (*stratwarm*). These alerts are issued by the IUWDS World Warning Agency or in certain circumstances by one of the solar-geophysical regional warning centres. The meteorological telecommunications network co-ordinated by the World Meteorological Organization carries the world-wide alerts once daily soon after 0400 U.T. Many geophysical stations in the various disciplines increase their programmes or carry on special experiments to take advantage of the special solar or geophysical conditions during the period of alert. Selections of *Retrospective World Intervals*, after a delay of a few months, are also announced by the World Warning Agency. An additional service of the regional warning centres is to notify geophysical and solar stations promptly (*Ursigrams*) with summary details of immediately significant geophysical observations and of major solar events which have important and sometimes long-lasting geophysical effects. The telegraphic addresses of the Regional Warning Centres are as follows:

Agiwarn Washington (U.S.A.); Dempa Tokyo (Japan); Nizmir Moscow (U.S.S.R.); Ionosphaere Darmstadt (G.F.R.) or Cnetagi Bagneux (France) or Agi Nederhorstdenberg (Netherlands). Associate Regional Warning Centres operate in some other localities.

(10) *The International Ursigram and World Days Service* (IUWDS) is a permanent scientific service of the International Union of Radio Science (URSI), with the participation of the International Astronomical Union and the International Union of Geodesy and Geophysics. IUWDS adheres to the Federation of Astronomical and Geophysical Services of the International Council of Scientific Unions. The IUWDS co-ordinates the international aspects of the world days programme and rapid data interchange, and also publishes subsequently an annual *Calendar Record* of solar and geophysical indices and events.

Recommended Scientific Programmes, Operational Edition

The following material was reviewed in 1965 by scientific working groups of the third Assembly of the IQSY Committee and the eighth Meeting of the Committee on Space Research as suitable for co-ordinated geophysical programmes in 1966.

(11) *Meteorology*. Particular efforts should be made to carry out an intensified programme on the *RGD*, each Wednesday, U.T. A desirable goal would be the scheduling of meteorological rocket sondes, ozone sondes and radiometer sondes on these days, together with maximum-altitude rawinsonde ascents at both 0000 and 1200 U.T.

During *WGI* and *Stratwarm* alert intervals, intensified programmes are also desirable, preferably by the implementation of *RGD*-type programmes on Mondays and Fridays, as well as on Wednesdays.

(12) *Geomagnetism*. It has always been a leading principle for geomagnetic observatories that operations should be as continuous as possible. Thus the great majority of stations taking part in the geomagnetic programme will

undertake the same programme without regard to the Calendar. The days marked on the Calendar will be of interest mainly to the following two types of geomagnetic stations: (*a*) stations recording quick-run micropulsations (with fast chart speeds) are requested to make such records on every *RGD* according to the following schedule: 1966 Jan. 5, from 1400 to 1800 U.T.; Jan. 12, from 1500 to 1900 U.T.; Jan. 19, from 1600 to 2000 U.T., etc. The observatories are not obliged to send their recordings to the World Data Centres except by special request (see IQSY *World Days Manual* under "Retrospective World Intervals on Micropulsations"). (*b*) Stations which, in addition to other activities, are equipped for making magnetic observations, but which cannot carry out such observations and reductions on a continuous schedule, are encouraged to carry out such work at least on *RWD* (and during times of *Magstorm* alert).

(13) *Ionosphere*. For the vertical incidence sounding programme, the summary recommendations are: (*a*) soundings to be made at 5-min intervals or less on *RWD* for stations normally making observations every 15 min or at more frequent intervals; all stations are recommended to make at least quarter-hourly observations on *RWD*; (*b*) *f*-plots are made for high-latitude stations and representative stations at lower latitudes for all days (that is, including *RWD* and *WGI*); (*c*) profile parameters *hc*, *qc* or recommended similar parameters to be determined and sent to *WDC* for *RWD* for all stations except those undertaking full profile programmes or producing monthly median profiles; (*d*) copies of hourly ionograms with appropriate scales for *PRWD* are to be sent to *WDC*; (*e*) stations in the eclipse zone should take continuous observations on solar eclipse days and special observations on adjacent days in accordance with detailed recommendations in *Ionosphere Manuals*. Continuous records of ionospheric parameters are acceptable in place of *f*-plots at temperate and low-latitude stations.

For the ionospheric drifts programme, observations are made at least on all *RWD* on all *WGI*, on every Wednesday (*RGD*) and on every Thursday (day following each *RGD*). Hourly tabulations for all days mentioned are sent to the *WDC*. It is essential that sufficient observations be made to provide representative values of the diurnal variations. Hourly tabulations for this purpose should also be sent to *WDC*.

For the ionospheric absorption programme, diurnal hourly observations are made on all *RWD* and hourly tabulations sent to *WDC*. Continuous observations are made on solar eclipse days, where possible, for stations in eclipse zone. Special efforts should be made to obtain additional absorption measurements at temperate latitude stations during the period of absorption winter anomaly, particularly on days of abnormally high or abnormally low absorption.

For back-scatter and forward-scatter programmes, observations should be made on all *RWD* at least.

For topside sounding experiments, it is recommended to send copies of records to *WDC* for all *RWD* at least.

It is recommended that more intensive observations in all programmes be considered on days of unusual meteor activity.

(14) *Solar Activity*. Observatories are invited to issue and send to the *WDC* of all disciplines special reports of their regular and any special observations on all solar eclipse days to assist in the interpretation of geophysical observations made in the eclipse zones. The total eclipse of November 12, 1966, although of relatively short duration, is of some special interest for astronomers and geophysicists since the path lies in low geomagnetic latitudes and near several long-established geophysical observatories.

(15) *Cosmic Rays, Aeronomy*. Research workers should take into account that observational effort in other disciplines tends to be intensified on the days marked on the Calendar, and schedule balloon and rocket experiments accordingly if there are no other geophysical reasons for choice.

(16) *Space Research*. In view of the variability of the *D* and *E* regions of the ionosphere, it is desirable to make rocket measurements of their characteristics on the same day at as many locations as possible. Where feasible, experimenters should endeavour to launch rockets on the Quarterly World Days (*QWD*) since these are also days when there will be maximum support from ground observations.

Copies of the Calendar are available on request to IUWDS, c/o Secretary General of URSI, 7 Place Danco, Brussels 18, or IUWDS, Deputy Secretary, Miss J. V. Lincoln, CRPL, National Bureau of Standards, Boulder, Colorado.

ANTARCTIC CREVASSE ACCIDENT

J. T. BAILEY, D. P. WILD and Dr. J. K. WILSON

ON October 12, 1965, a British Antarctic Survey tractor fell 150 ft. into a hidden crevasse when operating 250 miles inland from the coastal station at Halley Bay. In this tragic accident three men, J. T. Bailey, D. P. Wild and Dr. J. K. Wilson, lost their lives. A fourth man, J. Ross, a geologist, who was accompanying them with a dog team, brought the news to another field party which reported the accident by wireless.

Jeremy Bailey, son of Mr. and Mrs. A. Bailey, was twenty-four years old. After attending the Watford Grammar School, he read physics at the University of Bristol where he obtained his B.Sc. degree in 1963. He was president of the students' Physical Society during his final year at Bristol. His wide interests included music, scouting and other outdoor activities.

After graduating, he moved to the Scott Polar Research Institute in the University of Cambridge where he became a candidate for a Ph.D. degree and a member of Downing College. As a research student working on radio echo methods of sounding ice sheets, he took part in field trials in north-west Greenland during June–August 1964, as a member of the Scott Polar Research Institute group working in co-operation with United States scientists and personnel of the United States Army. For the latter part of these highly successful trials he had the sole responsibility for operating the equipment from the Scott Polar Research Institute. His natural enthusiasm and ability were evident, and greatly impressed his American colleagues. A preliminary note on this work appeared in *Nature* (204, 420; 1964).

From his arrival in Cambridge it had been planned that he should carry out a year's field research with the British Antarctic Survey. He sailed for Halley Bay in December 1964, since when radio reports have indicated that his work was progressing well. A 300-mile journey completed in April 1965 proved the effectiveness of recent improvements to the equipment and promised well for the inland trip in October, which ended so tragically. Publication of his results from Antarctica and Greenland will form an impressive memorial to the work which he enjoyed so much, but will not compensate for the loss of a young man so full of the promise of further achievement.

David Wild, son of Mr. and Mrs. Peter Wild, was twenty-four years old. He had been educated at St.

Asaph Grammar School and University College of Wales, Swansea, where he gained an honours degree in geography. All his life he had been a keen mountaineer besides being a Queen's Scout with much experience of camping and travelling. In 1961 he seized the opportunity to join his University expedition to Arctic Norway where his chief interest lay in the raised beaches and moraines. At the University he undertook additional courses to fit him for survey work in the Antarctic and finally joined the British Antarctic Survey as a topographical surveyor in 1963.

His evident qualities of leadership and his great good humour made him a popular member both on board ship and at his base. At the time of his death he was already in his second Antarctic year and would have returned in 1966 with an extensive coverage of the mountains at present being mapped. Unfortunately it is feared that most of this work was lost with him. Before leaving for the Antarctic he had presented a joint paper, with F. Solari, to the Photogrammetric Society entitled "Plane Table Photogrammetry with a Leica Camera in the Punjab Himalayas".

Dr. John Wilson, son of Dr. and Mrs. G. I. Wilson, was just twenty-nine. Born at Stafford he was educated at Bedales School and The Queen's College, Oxford, where he took his B.A. degree in animal physiology in 1959. The next three years were spent studying at Middlesex Hospital Medical School where he gained the degree of B.M., B.Ch.

Having qualified he successively held posts at Mount Vernon Hospital, Northwood, Middlesex Hospital and the Ipswich and East Suffolk Hospital.

In 1964 he volunteered for service in the Antarctic with the British Antarctic Survey. The next 5 months were spent at the Department of Human Physiology of the Medical Research Council, developing the research project he was to carry out at Halley Bay. This was chiefly concerned with variations in manual dexterity and sensitivity of touch in varying degrees of cold.

In December 1964 he sailed for Halley Bay, the most southerly of the British bases, where a ship can only pay a visit once a year. At the base he immediately became a popular and active member enthusiastically taking part in the general work besides following up his own research. Indeed, he became so keen that he applied to stay on for a second year, an application which was immediately accepted.

All these three men who were so tragically lost in their tractor were enthusiasts in their field and at the outset of careers which promised so well for the future. All young men who go to face the Antarctic require unusual strength of character, enthusiasm and dedication; these three excelled in them all.

NEWS and VIEWS

Theoretical Astronomy in the University of Sussex

THE Science Research Council is to make a grant of up to £33,500 to enable the University of Sussex to establish a research group in theoretical astronomy. The group will be led by Prof. W. H. McCrea, at present professor of mathematics in the University of London, Royal Holloway College. The group will form part of a joint programme of teaching and research by the University of Sussex and the Royal Greenwich Observatory at Herstmonceux. In this connexion, the University has made the following appointments: *Visiting Professor*, Sir Richard van der Riet Woolley; *Visiting Readers*, Dr. D. Lynden-Bell and Dr. B. E. J. Pagel. The University is to make an appointment to a further chair in theoretical astronomy.

Biochemistry in the University of Liverpool: Prof. J. Glover

DR. J. GLOVER, Leverhulme reader in biochemistry in the University of Liverpool, has been appointed to the newly established second chair of biochemistry in the University. Dr. Glover is forty-six years old, and was educated at the Royal Belfast Academical Institution and The Queen's University, Belfast, where he gained a first degree in chemistry in 1940 and a master's degree in 1941. During 1941–45 he served as an experimental officer in the Chemical Inspection Department of the Ministry of Supply, and was in charge of the analytical laboratories at Chorley and later at Woolwich Arsenal. During 1945–47 he held the Musgrave research studentship and a senior research grant from the Government of Northern Ireland at the University of Liverpool, where he undertook research on vitamin A. He was awarded a Ph.D. in 1948 and a D.Sc. in 1961 by the University of Liverpool. In 1947 he was appointed assistant lecturer in biochemistry at the University of Liverpool and was promoted lecturer in 1951, Leverhulme lecturer in 1955, Leverhulme senior lecturer in 1958 and reader in 1964. In 1950 he was appointed a Commonwealth Fund Fellow and worked at Washington University, St. Louis, and Columbia University, New York. Dr. Glover has lectured in Switzerland, Washington, and New Jersey, and in Stockholm, and has attended many international conferences in the United States and in various countries in Europe. He is a member of the committee of the Biochemical Society.

Improved Research Reactors

THE *Pluto* research reactor at Harwell is now running at 20 MW—twice the power for which it was designed. The reactor has been running at 15 MW since 1962, when the first improved fuel elements were used; a new type of fuel element was recently introduced and the reactor operated, in a series of experimental runs, at 22·5 MW. Parallel tests are being conducted in the 'Materials Testing Reactor' (a *Pluto*-type reactor) at Dounreay. The reactor is now using the new type of fuel element and will be operating at increased power early in 1966. The basic reason for increasing the power of these reactors is to increase the neutron density in them and thus to enable research workers from the Atomic Energy Authority to increase the number of experiments carried out on them each year. The new fuel element largely responsible for the increase in power consists of four concentric fuel tubes instead of the ten-plate assembly previously used. It was developed by engineers at Harwell and Dounreay in conjunction with the Production Engineering Research Association and Marston Excelsior, Ltd. The Harwell work also included the addition of four vertical quick-acting control rods within the fuel element and this form of control will be used in both *Pluto* and the Dounreay 'Materials Testing Reactor'. It is believed that these improvements could be adapted to any of the existing reactors of similar type, namely, *Dido* at Harwell, *Hifar* in Australia, *DR 3* in Denmark, and *FRJ-2* at Jülich, Germany.

French Satellites in Orbit

ON November 26 the French satellite, *A*-1, was successfully launched from Hammaguir in the Sahara by a three-stage *Diamant* rocket. France thus became the third nation to launch a satellite unaided. The *Diamant*

rocket is 19 m long and has an initial weight of 18·4 tons. The first stage, called *Emeraude*, is a liquid-fuel rocket which burns for 93 sec and has a thrust of 30 tons. The second stage (*Topaze*) is a solid-fuel rocket giving a thrust of 15 tons for 44 sec. The third stage, which burns for 45 sec, is also a solid-propellent rocket. The *A*-1 satellite itself, which has a mass of about 40 kg, did not carry any scientific experiments. But it did have a radio transmitter operating on 136·53 Mc/s; these radio signals ceased after a short time in orbit. The satellite, which received the international designation 1965–96*A*, entered an orbit with the following parameters: inclination to the equator, 34·2°; orbital period, 108·5 min; perigee height, 530 km; apogee height, 1,800 km; eccentricity, 0·084. The predicted lifetime in orbit is about 100 years. Ten days later another French satellite, *FR*-1*A*, was launched by the United States National Aeronautics and Space Administration, under an international agreement similar to that for the British satellites, *Ariel* 1 and 2. The *FR*-1*A* satellite weighs 61 kg and has been designated 1965–101*A*. The main experiment, designed by the Centre National d'Etudes des Telecommunications, is concerned with the propagation of very low-frequency radio waves. A second experiment, provided by the University of Birmingham, consists of a probe to measure electron density. The *FR*-1*A* satellite is in a near-circular orbit at a height of about 750 km, the inclination to the equator being 75·8°.

Ministry of Technology: Regional Organization

In answer to a further question on December 7, the Minister of Technology, Mr. F. Cousins, said that he had established a strong regional organization, one of the main tasks of which was to promote the more vigorous application by industry of new scientific and technical knowledge resulting from research financed or sponsored by the Government. It was examining the limitation of the supply of information from the research associations to supporting firms and also the method by which information was disseminated through the Ministry's establishments. The establishment of the Ministry's regional offices was almost complete: new offices were opened during October in Birmingham, Bristol, Leeds, Manchester and Nottingham, and a further office for South-East England and East Anglia would be opened early next year. By the end of 1967, the Ministry would have set up a network of about seventy liaison centres, co-ordinating the activities of industry, education and the Government, and the regional officers would be represented on the regional planning bodies. At the end of June, the National Research Development Council had 95 development projects in hand; 17 new projects had since been authorized and a further 120 were being assessed. The Ministry's commitments on development projects exceeded £8 million.

Metric Screw Threads

In an answer in the House of Commons on December 7, the Minister of Technology, Mr. F. Cousins, stated that the International Organization for Standardization had reached agreement on recommendations for general-purpose screw threads comprising a system of metric threads and another of inch threads, which was the same as the existing Unified threads. These two systems had been published as British Standards *B.S.* 3643 and *B.S.*1580. Three general-purpose screw thread systems were used in Britain to-day, namely, Whitworth, B.S.F. and B.A. They were little used outside Britain, and to perpetuate their use would be to increase the costs of, and hamper, British export trade. The British Standards Institution had recently issued an important policy statement urging British industry to adopt the International Organization for Standardization metric system wherever possible in future designs. The statement had received strong support from industry, and the decision to recommend the use of metric screw threads had the full support of the Minister, although, with the British Standards Institution, he recognized that certain sectors of industry might find it necessary to continue to use the Unified Inch system for some time. The Institution's statement implied that the Whitworth, B.S.F. and B.A. threads were now to be regarded as obsolescent, although their replacement would be gradual and supplies of screws and tools to the obsolescent standards would be maintained for many years, for servicing designs and equipment already installed. He also supported the Institution's view that these systems should be superseded by metric threads in preference to an intermediate change to the standard inch threads. More than 80 per cent of the population of the world was in countries which had adopted or were adopting the metric system, and British trade with these countries was expanding faster than that with countries not using the metric system.

National Computing Centre

Again, in a statement to the House of Commons on December 7, Mr. F. Cousins said that a National Computing Centre was to be established. This should reduce wasteful duplication of programming by providing users of computers with information about programmes already available in its library and elsewhere. The Centre would also develop and sponsor the development of programmes designed to serve users having closely similar tasks. It would provide and encourage training in systems analysis, programming principles and applications of computers. It would promote research into methods of programming and operating computers and into the influence of these methods on the design of computers. These objectives would be pursued in close co-operation with the manufacturers of computers and with users in industry, commerce, administration, science and technology. The Centre would be established as an independent non-profit-making company, limited by guarantee. Mr. Cousins said he would be inviting representatives of manufacturers, users and of professional and other bodies to become members of the Centre and to serve on its Council. Prof. Gordon Black was being released by the Atomic Energy Authority to become the first director of the Centre, but he would retain his appointment as part-time professor of automatic data processing at the University of Manchester. Mr. Cousins hoped that the Centre would be built in Manchester on a site close to the University, and that it would be fully in operation by 1967. The Centre would probably require a staff of between 40 and 50, who would not be Civil Servants and would need to be experts. It was intended that the Centre should have a computer.

Dublin Institute for Advanced Studies

The Dublin Institute for Advanced Studies recently celebrated its silver jubilee. Established in 1940 by Act of the Irish Parliament, its aims, as laid down in the Act, are the furtherance of advanced study and the conduct of research in specialized branches of knowledge and the publication of the results of such study and research. These aims are carried out through its constituent schools, two of which, the School of Celtic Studies and the School of Theoretical Physics, were established in November 1940 and are specifically mentioned in the Act. A third School —the School of Cosmic Physics—was established in 1947. The School of Celtic Studies is now universally recognized as the foremost centre for research in all branches of that subject. The School of Theoretical Physics has had on its staff such eminent physicists as Dr. Erwin Schroedinger and Dr. Walter Heitler, and now has, as senior professors, Dr. J. L. Synge and Dr. Cornelius Lanczos. The first senior professors in the School of Cosmic Physics were the late Prof. L. W. Pollak, Dr. H. A. Brück (now Astronomer Royal for Scotland) and Dr. Lajos Janossy (now at Buda-

pest). The late Dr. M. A. Ellison succeeded Dr. Brück as senior professor in the Astronomical Section, and the present senior professor is Dr. P. A. Wayman, formerly of the Royal Greenwich Observatory. Dr. Janossy was succeeded by Dr. Cormac Ó Ceallaigh as senior professor in the Cosmic Ray Section, and Mr. Thomas Murphy succeeded Dr. Pollak as senior professor in the Geophysical Section. A duty laid down for all constituent schools is the training of advanced students in methods of modern research, and scholars from all five continents have studied at the Institute. The extent and quality of the research carried out in the Schools can be assessed by reference to the works published by members of the staff and the numerous papers by both staff and scholars which have been published in leading scientific journals and periodicals. An informal celebration of the silver jubilee was held in the Royal Irish Academy, Dublin, on November 16, at which the President of Ireland, Mr. de Valéra, who as Prime Minister was responsible for the setting up of the Institute, was the guest of honour.

Journal of Zoology

THE *Proceedings of the Zoological Society*, now published as the *Journal of Zoology*, being the Proceedings of the Zoological Society of London, publishes papers on all aspects of zoology, including systematics. In particular, it aims at publishing papers on the more general aspects of biology which do not fall within the province of the more specialized journals. The *Journal* has recently increased its number of pages and is able to accept papers of rather more than usual length, although, of course, it in no way encourages prolixity, and places quality before quantity. Traditionally the *Journal* specialized in systematic and morphological subjects; but it has now widened its scope to be a true journal of zoology, and a glance at the issues for recent years shows that ecological, physiological and ethological papers are now included, dealing with all phyla of the animal kingdom. Papers are published by workers in universities and research institutions from all parts of the world, provided they are of sufficient standard.

Journal of Cell Science

THE *Quarterly Journal of Microscopical Science*—one of the oldest British biological journals—is changing its title to *Journal of Cell Science*, with effect from 1966. It has for many years been publishing work on cells, being, in fact, one of the few journals in Britain to do so. The decision to concentrate exclusively on cytology was taken three years ago, and since that time the proportion of papers on histological and micro-anatomical topics, which at one time figured prominently in its pages, has gradually been reduced. The *Journal of Cell Science* will deal with the study of cell organization in all its aspects, publishing papers on the structure and functions of cells at all levels of analysis and including material on such topics as cell growth and division, cell movements and interactions, and cell genetics. Contributions on microorganisms and viruses will be accepted, in so far as they are relevant to an understanding of cell organization, and accounts of new techniques will be published. The journal is to have a new format and page size and will be published by the Cambridge University Press. The editors, Prof. H. G. Callan and Dr. A. V. Grimstone, will in future be assisted by an editorial board. The volume of research on cell biology in Britain is steadily increasing, and the need for a wide-ranging journal in this field has been felt for some time. It seems likely that the *Journal of Cell Science* will go far towards filling this need.

The Soils on Quaternary Beach Ridges in South Australia

CALCAREOUS beach sands are found in some thirty ridges about 50–100 ft. high, running sub-parallel to and up to 60 miles inland from the coast of the south-east of South Australia. The soils derived from these sands and from estuarine and lacustrine deposits are the subject of an interesting study by G. Blackburn, R. D. Bond and A. R. P. Clarke entitled *Soil Development Associated with Stranded Beach Ridges in South-east South Australia* (Australia: C.S.I.R.O. Soil Publication No. 22. With an Appendix by N. H. Ludbrook. Pp. 66 + 4 maps. Melbourne: C.S.I.R.O., 1965). The genetic status of the soil horizons has been established by the cumulative size-frequency distributions of the sand fractions (0·02–2·00 mm) and detailed consideration is given to the problem of accounting for the diversity of the main soil types in a region where the present climatic variation cannot be a major factor. The quaternary calcareous beach sands are not of aeolian origin but may occur as flat-bedded layers or as massive coastal dunes; the absolute ages of the ridges have not been determined, but it is probable that they have resulted from upwarping and from glacial–eustatic-sea-level changes. The four soil types described are: (1) podzols, characteristic of those in other parts of the world; (2) terra rossa which are not developed directly from hard limestone; (3) ground-water rendzinas which are variable in profile features; and (4) solodized solonetz which may display the morphological features commonly described but sometimes resemble the solonetz.

Coal Petrology

THE petrography of coal has had a long, chequered and controversial history of technical evolution, largely because different investigators over the years have adopted different techniques in examining, identifying, describing, and reducing to a universally accepted philosophical classification, optically distinguishable entities in coals. Most coals derive from plant accumulation in swamps; remnants of these plants are observed in coals, but were undoubtedly much altered during geological time by periods of compression and thermal conditions caused by blanketing under later sediments. Different parts of original plants have altered in different ways; thus, microscopical examination tends to show varying optical properties from point to point, often in the same thin coal section. With high magnifications, few areas of coal sections are seen to be homogeneous; with low magnifications, even visual examination, most coals reveal distinct layering of apparently similar materials. These are some of the practical difficulties encountered in petrographic investigations of coals, throughout the range of brown coal to anthracite. But despite this, in alliance with chemical, physical and technological examinations, petrological evaluations of coals have become an increasingly popular and valued tool both in coal research and industry. This is the theme of an excellent paper by C. F. K. Diessel and T. G. Callcott, entitled "Petrographic Features of New South Wales Coking Coals" (*The B.H.P. Technical Bulletin*, 23, 9, No. 2; August 1965. The Broken Hill Proprietary Co., Ltd., Melbourne, Australia). Although the purport of this paper is an appraisal of the petrographic and chemical composition of New South Wales coking coals, its value goes far beyond this, in that it examines contemporary systems of coal petrology now in vogue internationally and pin-points the still existing difficulties in the nomenclatures involved, despite the valuable publication of the *International Handbook of Coal Petrology, 1963*. This present paper includes a table of five different but co-related systems of nomenclature in coal petrology (macerals); these are: Thiessen–U.S. Bureau of Mines; B.H.P. System as used at present; Geological Institute of the Academy of Science, U.S.S.R.; Spackman System; and the Stopes–Heerlen System. As the authors remark, conversion from one of these systems to another is by no means a simple matter; apart from different techniques used in analysis, widely differing points of view prevail on the essentials of a descriptive basis for coals. The problems facing the International

Q 343

Committee on Coal Petrology in its attempts to standardize terminology have been, and still are, quite formidable. From a purely petrographical standpoint, although the optical identification of many components of coals has advanced considerably in recent years, compared with the days when 'clarain', 'durain', 'fusain' and 'vitrain' were the common labels (Stopes), there still remain problems of determining the ultrafine structure and molecular constitution of the now recognized components, and of relating these features to the physical properties of the many coal-types concerned.

Palaeontology in the U.S.S.R.

The recent volumes of the *Transactions of Palaeontological Institute (Moscow)* are: (103) *Corynexochoidea Trilobites and their Historical Development*, by N. P. Suvorova (1964); (104) *Tertiary Homoptera of Stavropol Region*, by E. E. Bekker-Migdisova (1964); (106) *Morphology, History of Development and the System of Ordovician and Silurian Bryozoa*, by G. G. Astrova (1965).

High-temperature Studies on Blast Furnace Slags

With the aid of differential thermal analysis and X-ray diffraction methods, the devitrification of solid glassy blast-furnace slag and crystallization of molted slag have been investigated in South Africa by J. E. Krüger, K. H. L. Sehlke and J. H. P. van Aardt, of the Materials Division, National Building Research Institute, C.S.I.R., Pretoria (*Reprint from Cement and Lime Manufacture*, 37, Nos. 4 and 5; July and September 1964. C.S.I.R. reference *R/Bou* 120). When vitreous blast-furnace slags are heated to 800°–900° C, devitrification takes place; the heat evolved during this process can be clearly seen on a differential thermal analysis curve, of which several examples are given in their paper, *High-Temperature Studies on Blast Furnace Slags*, by the authors concerned. It was found that for the ten samples of slag selected (seven of them South African), the appearance of the differential thermal analysis thermograms differed from slag to slag, even if the chemical compositions of the slags were similar; that when the slags were heated to temperatures corresponding to different points on the differential thermal analysis thermograms and subjected to X-ray diffraction analysis, analogous with the process of slow cooling of slag, different crystalline phases formed during devitrification; the latter are identified. Further, there is marked agreement between phases of a slag formed after complete devitrification and phases emerging after slow cooling of the molten slag to ambient temperatures. Two other significant conclusions arise from these investigations: slags possessing poor hydraulic properties would, on complete devitrification, give phases of low calcium content, such as pseudo-wollastonite and diopside, indicating a low calcium potential for such slags; and devitrification differential thermal analysis peaks persist even after the slags have been subjected to hydration for prolonged periods. This paper is worthy of study by all workers in the field of slag-mineral analysis, particularly as regards recognition and identification of mineral phases with change of state.

Handbook of Seed Health Testing

The *Handbook of Seed Health Testing*, issued by the International Seed Testing Association (I.S.T.A.), comprises four series of papers as follows: Series 1, general topics; Series 2, seed pathology of a particular crop or a group of organisms; Series 3, working sheets, each dealing with one seed-borne disease—the methods being based on co-operative work over the past 8 years by the Plant Disease Committee of I.S.T.A.; Series 4, description and illustrations of seed-borne fungi. The papers are first being published from time to time in the *Proceedings of I.S.T.A.*, and then reprinted so that they are available for general purchase. Thus, Chapter 1 of Series 1 is an annotated list of seed-borne pathogens published, in this case jointly, by the Commonwealth Mycological Institute, Kew, and I.S.T.A. in 1959; and Chapters 2–4 give information on seed weakness, pesticide treatment and a review of methods; of Series 3 the first 33 working sheets have been prepared (loose-leaf in binder), the host plants including wheat, rice and sesame; and, as noted in *Nature* (207, 579; 208, 319; 1965), the first papers of Series 4, descriptions and illustrations of 77 seed-borne fungi found mainly on oats and flax, have been compiled by Malone and Muskett. A colour transparency scheme is planned in connexion with Series 3 to help with recognition of seedling symptoms. The *Handbook* thus replaces the *Manual for the Determination of Seed-borne Diseases*, by Dr. L. C. Doyer, of the Wageningen Seed Testing Station, published in 1938 under the aegis of I.S.T.A. This, the only work of its kind, is now unobtainable. Those parts of the new *Handbook* already completed cost approximately 40 guilders (£3 sterling, 8.5 dollars) (half-price to members of I.S.T.A.), and are available at the I.S.T.A. Secretariat, Binnenhaven 1, Wageningen, Netherlands.

Aureomycin and the Cultured Pearl Industry

Japan to-day produces some 400 million cultured pearls per annum, of which 97 per cent are exported. It is a fact that the 'natural' pearls discovered now play a relatively insignificant part in the world market. It was towards the end of the nineteenth century that a Japanese, Kokichi Mikimoto, first hit on a successful technique for 'seeding' and caring for oysters, from which the idea of the cultured pearl gradually took shape; he patented his process and started to export this 'natural' product. Mikimoto was successful in a lawsuit that followed, in the course of which biologists at the time, who had tested both his and natural pearls, reported that there was no difference between them. Thus the cultured pearl industry grew apace. Japanese oyster farms are located in selected estuaries, where specially bred oysters are seeded with round beads manufactured from shells of what are called 'pigtoe mussels', most of the latter being derived from the Mississippi and Tennessee Rivers in the United States. Maturity of the pearls thus formed takes from three to five years, depending on the size of the pearls sought. But until comparatively recently, only three out of five oysters produced some sort of pearl, and only one out of every twenty pearls was considered up to top standard ('hanadama' or 'tears of the moon', as they are known in Japan). About 5 years ago the problem of improving yields and quality of these cultured pearls was investigated at the Fisheries School of Mie Prefecture in Japan, by a research team headed by Tetsuo Miyauchi. Starting with the theory that bacterial infections at seeding time were responsible for poor yield, misshapen or discoloured pearls, experiments were begun with applications of Lederle's broad-spectrum antibiotic, 'aureomycin chlortetracycline', in an effort to halt these infections. These trials were eminently successful. After four years of tests, this technique resulted in a 30 per cent increase in yield of top-quality 'hanadama' pearls and a significant increase in the total number of pearls obtained. This somewhat unusual application of a modern antibiotic is briefly described in an article, "Pearls: 'Tears of the Moon'" (*Cyanamid International Newsletter*, 4, No. 4. Cyanamid of Great Britain, Ltd., Bush House, Aldwych, London, W.C.2). The Japanese affiliate of Cyanamid, Ltd., Lederle (Japan), Ltd., has prepared a new formulation of 'Aureomycin' for the cultured pearl industry, known as 'Pearl-up' (chlortetracycline), designed to boost production on a world-wide scale.

Hospital Libraries

A pamphlet, *Hospital Libraries*, issued by the Library Association (*Hospital Libraries: Recommended Standards*

for Libraries in Hospitals. Pp. 16. London: Library Association, 1965. 5*s.*; L.A. members, 3*s.* 9*d.*) outlines recommended standards for libraries in hospitals. These cover planning libraries in hospitals, general library service for patients and staff, medical libraries in a regional board area, the functions of the library in a non-teaching hospital and libraries in training schools for nurses. There is a short list of books.

Commonwealth Universities

THE ninth edition, August 1965, of the *List of University Institutions in the Commonwealth*, first issued by the Association of Commonwealth Universities in 1949 (Pp. 12. London: The Association of Commonwealth Universities, 1965, *gratis*) is based on information collected in June 1965, and entries altered since the eighth edition (June 1964) are distinguished by a special mark. Full postal addresses are given. Schools of the University of London are listed in an appendix, while a second appendix lists universities in Eire and the Republic of South Africa.

Eye for Isotopes

THE Atomic Energy Authority's film, *Eye for Isotopes*, has been awarded a Special Diploma at the fourth International Festival of Scientific–Technical Films organized by the Yugoslav society "Nikola Tesla" in Belgrade. Some 200 films were presented at the Festival and only 13 awards were made. *Eye for Isotopes*, which runs for 27 min, was designed to encourage industrial audiences to consider how radioisotopes might be applied to their processes to save both time and money, by illustrating some of the now well-established techniques. Produced by Clifford Parris and directed by Derek Conrad, of World Wide Pictures, Ltd., and with Dr. John Putman, of the Authority's Wantage Research Laboratories, as technical adviser, *Eye for Isotopes* was awarded a first prize at the fourth International Film and Television Festival in New York in 1964 and also an Award of Merit at the International Science Film Festival in Toronto, also in 1964.

University News: Liverpool

PROF. T. W. GOODWIN, professor of agricultural chemistry in the University College of Wales, Aberystwyth, has been appointed to the Johnston chair of biochemistry as from October 1, 1966, on the retirement of Prof. R. A. Morton. A. Kirk has been appointed director of the Computer Laboratory. The following lecturers have also been appointed: Dr. H. J. Phillips (anatomy); H. Kinloch (mechanical engineering); Dr. K. N. Strafford (metallurgy).

London

PROF. W. R. MEAD, professor of geography at University College, has been appointed to the headship of the Department and chair of geography tenable at that College. The following professors have also been appointed: Dr. G. G. Meynell (Guinness chair of microbiology, tenable at the Lister Institute of Preventive Medicine); Prof. J. H. Westcott (control systems, tenable at the Imperial College of Science and Technology); Prof. P. Wheatley (geography, tenable at University College). The following titles have been conferred: *Professors*, Dr. M. J. Smith (biochemical pharmacology, in respect of his post at King's College Hospital Medical School); Dr. R. A. Shaw (chemistry, in respect of his post at Birkbeck College); *Readers*, Dr. J. F. A. P. Miller (experimental pathology, in respect of his post at the Institute of Cancer Research); Dr. P. A. Nasmyth (pharmacology, in respect of his post at St. Mary's Hospital Medical School); Dr. D. Wilkie (botany), in respect of his post at University College).

Newcastle upon Tyne

PROF. J. HOUSE has been appointed to the headship of the Department and the chair of geography on the retirement of Prof. G. H. J. Daysh. The following appointments have also been made: *Senior Lectureship*, Dr. M. G. McEntegart (microbiology); *Lectureships*, Dr. R. M. Keenlyside (physiology); J. D. Arthur (mechanical engineering).

Strathclyde

DR. D. W. A. SHARP, reader in inorganic chemistry in the Department of Pure and Applied Chemistry, has been appointed to the chair of inorganic chemistry from October 1.

Announcements

PROF. B. GREGORY has been appointed director general of CERN, the European Organization for Nuclear Research, in succession to Prof. V. F. Weisskopf, who has retired after 5 years' service and is returning to the Massachusetts Institute of Technology as Institute professor of physics.

DR. J. A. STRATTON is retiring as president of the Massachusetts Institute of Technology on June 30. He has been elected chairman of the board of trustees of the Ford Foundation as from January 1, on the retirement of Mr. J. J. McCloy.

DR. S. WORTMAN, formerly director of the Pineapple Research Institute, Hawaii, has been appointed director for agricultural sciences in the Rockefeller Foundation.

A SYMPOSIUM on "Recent Advances in Polymer Chemistry", arranged by the Bradford Chemical Society, will be held at the Bradford Institute of Technology on February 5. Further information can be obtained from Mr. W. A. Straw, Department of Chemical Technology, Bradford Institute of Technology, Bradford 7.

A DISCUSSION on "Operating Experience with Deck Machinery", organized by the Power Division Professional Group on Road, Air and Sea Transportation of the Institution of Electrical Engineers, will be held at the Institution in January 5. Further information can be obtained from the Institution of Electrical Engineers, Savoy Place, London, W.C.2.

THE seventeenth Pittsburgh conference on "Analytical Chemistry and Applied Spectroscopy" will be held in Pittsburgh during February 21–25. The programme will include the following symposia: combined gas chromatographic–mass spectrometric techniques; fast reaction kinetics; electron spin resonance; electron microprobe; process control X-ray spectrometry, atomic absorption; Coblentz Society symposium; gas chromatography utilizing pyrolytic techniques; nuclear magnetic resonance spectra of polymeric materials; nuclear magnetic double resonance; magnetic optical rotatory dispersion; analytical instrumentation in the space programme; new instrumentation techniques. Further information can be obtained from Dr. R. E. Hein, Seventeenth Pittsburgh Conference, Inc., Mellon Institute, 4400 Fifth Avenue, Pittsburgh, Pennsylvania.

ADDENDUM. The publication, *Enzyme Nomenclature. Recommendations (1964) of the International Union of Biochemistry on the Nomenclature and Classification of Enzymes, together with their Units and the Symbols of Enzyme Kinetics*, referred to in ref. 1 of the article entitled "Enzyme Nomenclature", which appeared on p. 736 of the November 20 issue of *Nature*, has also been published as a paperback book and is available in Great Britain from the Elsevier Publishing Co., Ltd., at a price of 18*s.*

ERRATUM. In the article entitled "Precipitin Activity in the Sera of Patients with Deficiency of β-Lipoproteins (Acanthocytosis)", by Dr. R. F. Murray, jun., and Prof. B. S. Blumberg, which appeared on p. 357 of the October 23 issue of *Nature*, the asterisk placed by the name of Prof. Blumberg should have been placed by the name of Dr. R. F. Murray.

INHALED PARTICLES AND VAPOURS

FIVE years ago, at Oxford, the British Occupational Hygiene Society organized an international symposium on inhaled particles and vapours (*Nature*, 186, 524; 1960); a second meeting was held at St. John's College and the Engineering Laboratory, Cambridge, during September 28–October 1, 1965. Forty-seven papers were presented, of which only one dealt with a vapour. Some 300 scientists and doctors attended the symposium, about half of them coming from abroad.

The papers were issued as pre-prints and divided into seven sessions. Prof. B. Pernis of Milan gave the Earl King Memorial Lecture and spoke about immunological reactions and pulmonary dust disease; the lecture will be printed in *Annals of Occupational Hygiene*, 9, Part (ii).

Attention was directed, in the opening paper by A. Policard, A. Collet and C. Reuet-Normand, to the advantages of using cats for inhalation experiments; unlike those of the rodents commonly employed, the lungs of cats are similar to those of man in having only one or two orders of respiratory bronchioles followed by well-developed alveolar regions. Dust deposits form around the bronchioles and the vascular system, as in man, and dust nodules may develop. An apparatus for recording physiological data from experimental animals was described by S. Laham and G. F. Dowd.

E. G. Tombropoulos had prepared and centrifuged homogenates of the spongy tissue of animal lungs containing acetate-^{14}C. The labelled acetate was found to preponderate in the fraction rich in mitochondria, which are believed to transform short-chain fatty acids into long ones. The long-chain acids are incorporated in lung phospholipids which are responsible for maintaining the patency of the alveoli by concentrating at the surface of the alveoli.

An investigation of mucous flow in the human nose was reported by D. F. Proctor and H. N. Wagner; a small quantity of radioactive material was placed on the surface of the nasal mucosa and its movement plotted by a double collimated crystal detector; movement was towards the nasopharynx which was reached in about 8 min, clearance being completed in 10–30 min. Measurements of air flow in a model of the human nose showed that large areas of mucosal surface were only slightly ventilated and that turbulence was low.

The volumes of air inhaled by coal-miners engaged in various occupations had been measured by G. G. Hadden, C. O. Jones and D. C. Morgan. Minute volumes varied from 10 l. up to a maximum of 54 l. for a coal-filler using a hand pick. Some association was noted between peak activity and peak dust concentration on hand-worked faces but was not apparent in mechanized areas.

The second session, dealing with pulmonary response to dust, opened with an account of a quick-freeze method of locating changes in the size of airways caused by the inhalation of a histamine aerosol by cats. Constriction of terminal bronchioles and alveolar ducts was observed. Some reaction occurred in bronchioles as large as 0·4 mm diameter; deposition in these may have been due to the fine aerosol particles having increased in size by absorbing water vapour. This work was carried out by J. A. Nadel, M. Corn and associates.

The effects of textile dusts were described by A. Bouhuys and P. J. Nicholls, who incubated human lung tissue with various substances and measured the production of histamine. Cotton dusts were active with human but not with animal lung. The bracts of the cotton boll gave a potent extract. Compound 48/80 released histamine in human and animal lung tissue. Similar substances, when breathed as aerosols, produced respiratory reactions in some ways analogous to those produced in the culture experiments, again implicating cotton bracts as a cause of at least part of the symptoms of byssinotic cotton workers.

W. T. Ulmer, in a series of measurements of human respiratory resistance, showed that the response to dust inhalation was similar whether or not the subject had experienced occupational exposure.

Three papers dealt with silica dust. A. Swensson utilized intratracheal injection of saline suspension into rats to illustrate how the lung reactions to silica dusts differed, even between amorphous silicas. Reactions in both lungs and lymph nodes were graded histologically and, also, by collagen production. P. Gross and H. Brieger, also injecting rats, found that coesite dust and quartz dust caused inflammation of the alveolar membrane but not of the interstitium; lesions were mainly located in the proximal part of the racemus and might tend to trap the dust there. Finally, I. Webster, M. C. Path and associates injected silica suspensions intravenously into rabbits and guinea-pigs to produce silica shock; an increase in the kinins of the blood resulted. Silica shock could be prevented by the administration of anti-amine drugs, the most effective of which also depressed the solubility of silica. The non-lipoid fraction of alveolar macrophages, collected after the animal had breathed silica dust, produced a granuloma when inoculated into animals. This effect appeared to be associated with abnormal contents of histamine and of an unidentified reagent. It is suggested that silica may stimulate the release of a cellular product, similar to that produced by a carcinoid tumour, which causes fibrosis in the peripheral part of the silicotic nodule.

Observations of the cytotoxic action of silica on macrophages were described by A. C. Allison, J. S. Harington *et al.*, who also showed a remarkable time-lapse film to illustrate their conclusions. Particles engulfed by a macrophage are held in a phagosome to the membrane of which lysosomes adhere and release enzymes into the phagosome. Silica particles, perhaps by forming silicic acid, cause the phagosome membrane to become permeable so that the enzymes escape into the cytoplasm of the macrophage and destroy it. Polyvinylpyridine-*N*-oxide prevents this from happening by forming hydrogen bonds with silicic acid.

It has been claimed that calcium fluoride dust has high fibrogenic activity; A. J. de Villiers and P. Gross set out to check this by the intratracheal injection of rats. The dust was found to cause no significant pulmonary fibrosis. In some animals the chest was exposed to X-rays, which caused characteristic effects but had no influence on alveolar clearance when irradiation took place six weeks before the inhalation of dust.

F. J. Strecker experimented with rats inhaling various kinds of silica dust and also some inert dusts. This work suggested that there was a high mitosis rate of alveolar cells, which are turned over about once a week; the considerable surplus of cells is eliminated via the bronchial epithelium and is easily capable of phagocytosing a great number of dust particles. The inhalation of dust does not produce an extra proliferation of cells since the normal turnover is quite adequate to deal with such an emergency. Silicosis-producing dusts kill the cells and cause an increase in the mitosis rate in alveolar regions; there appears to be difficulty in eliminating cell debris via the bronchioles. This may mean that some cell debris penetrates the interstitium and attains the lymphatic vessels. Treatment of animals with polyvinylpyridine-*N*-oxide prevents cell necrosis due to silica. Different dusts and different species of animals yield differing elimination rates, but the over-riding rule that greater cytotoxicity causes greater translocation to the lymphatics seems to hold. Further

experiments using intraperitoneal injection supported this view.

A. Collet, J. C. Martin and colleagues described investigations of alveolar macrophages obtained by washing out animal lungs. The cells from different species and from man were similar in many respects and all had characteristics which were unique among pulmonary cells and indicated evolution from a small non-phagocytic lymphocyte. A non-pulmonary origin of macrophages is therefore a possibility, with lymphoid tissue as a likely alternative source. The ingestion of particles caused iron to accumulate in the cells.

A number of papers dealt with lung clearance in animals; after studying the deposition of dusts in rats by visual microscopy it was concluded, by P. Gross, E. A. Pfitzer and T. F. Hatch, that by about four days after exposure the peripheral region of the racemus is cleared of dust but that there is a build-up of deposit in the proximal region due partly to transport from the periphery and partly to initial deposition there. The proximal region comprises the respiratory bronchioles and alveolar ducts with directly associated or evaginating alveoli. The surface area of the proximal zone is only about one five-hundredth of that of the whole racemus, so that concentration of the dust, which was well distributed at initial deposition, is inevitable. It is the dust situated in the racemus that is responsible for the protracted clearance by the bronchial epithelium; the entire journey along the ciliated tract occupies only about 24 h, so that dust recovered from the bronchi and bronchioles after several days must have come from the deposits building up at the base of the mucous escalator in the necks of each racemus.

J. Ferin exposed rats to silica dust and analysed groups of lungs after 18 h for initial deposition and after 25 days to establish lung clearance. He demonstrated that the clearance of dust from the lungs was diminished if the animals were exposed to cold for long periods before and after inhaling dust, but that stress induced by injecting solutions of formaldehyde had no effect.

Short-term lung clearance in rabbits, after they had inhaled an aerosol consisting of radioactive plastic spheres 6μ and 3μ in diameter, was described by B. Holma. After exposure to the aerosol, the animals were scanned periodically from head to abdomen with an opposed pair of collimated crystal counters and the transfer of activity from thorax to abdomen was clearly shown. An initial rapid clearance from the thorax lasted up to 4 h from exposure, for the 6μ particles, but was much slower for the 3μ ones, presumably because more of them were deposited in alveoli, although this is not discussed. A secondary, much slower, clearance of residual activity followed. This had a half-life of about 70 h for the larger particles and 210 h for the smaller.

T. G. Morris, W. H. Roberts *et al.* compared the retention of asbestos and silica dusts in specific pathogen-free rats and normal rats. W. Klosterkötter and H. J. Einbrodt, also using rats, studied elimination, following the breathing of various dusts including highly dispersed forms of silica. Quartz dust was found to suppress the elimination of an inert dust. Aerosil, a hydrophilic colloidal silica, was eliminated rapidly, probably because of its high solubility, but hydrophobic forms of colloidal silica disappeared much more slowly and collected in the lymphatics.

Experiments on the removal of bacteria from the lungs of mice were discussed by G. Green and E. H. Kass. Using aerosols of radioactive bacteria and comparing the number of viable organisms with the quantity of radiation, it was established that killing of the bacteria occurred long before physical removal of the debris. A technique utilizing fluorescence made it possible to show that organisms were picked up by phagocytes in the alveoli; phagocytes could be found on the bronchial mucosa in the course of transportation out of the lungs several hours after administration. A lowering of the clearance rate when animals were stressed by hypoxia, ethyl alcohol starvation and cortisone was demonstrated. Different species of bacteria had different clearance rates.

Experiments aimed at elucidating prophylaxis against silicosis had been carried out by B. Rasche and W. T. Ulmer. After exposing guinea-pigs to dust, separable alveolar cells were washed out of the lungs with saline and incubated in culture media; the number of cells, their oxygen consumption and the production of lactic acid were measured. The breathing of quartz dust stimulated the production of macrophages, which was further enhanced if an aerosol of aluminium chloride was also inhaled. Aerosols of chlorides of iron, magnesium and calcium had no such effect, nor did aerosols of polyvinylpyridine-*N*-oxide the action of which, in inhibiting silicosis, cannot, therefore, be associated with elimination of dust.

W. J. Bair and J. V. Dilley failed to detect any cigarette smoke influence on the pulmonary clearance of radioactive dusts of iron oxide and chromium oxide from the lungs of rats and dogs. Deposited dust was assessed by scanning the animals with crystal counters.

Investigations of the lung burden of animals exposed in a field experiment were described by R. H. Wilson and J. L. Terry. The dust clouds contained a trace of plutonium and covered a very wide range of particle size, with mean mass diameters of 10–20μ. Initial deposition, following exposure to a bomb burst on a hard surface, was about the same in several species, but the lung burdens remaining after a lapse of several days were much less in sheep than in dogs. The short-term lung clearances had half-times of the order of several days, rather than the 24 h often quoted, and were followed by a long, slow decay extending beyond a year. The latter accounted for a residual 15 per cent of respirable material in dogs, 5 per cent in burros and only 1 per cent in sheep. The burro is assumed to be the best approximation to man.

When the dust of uranium ore is inhaled the secular radioactive equilibrium of the decay nuclides will not be maintained in the lungs if the various daughter products are subjected to differing biological rates of elimination. This was investigated by B. O. Stuart and T. M. Beasley, to see if the permissible level for pitchblende dust in the air of mines needed modifying, due to the building up of ^{230}Th in lung deposits on account of its relatively slow elimination compared with the parent radionuclide. Experiments with rats inhaling pitchblende dust over eight weeks revealed a gradual disproportionation of uranium and thorium, the proportion of the latter being higher, both in lung parenchyma and in the lymph nodes. Translocation to kidney, femur and liver ultimately led to 50 times more thorium being detected due to selective removal of uranium. The hazard from inhaling natural uranium, therefore, needs to be evaluated with separate allowance for the daughter products.

The fifth session, dealing with inhalation by man, was opened by the sole paper about vapour; this was by A. Morgan, D. J. Morgan and G. M. Arkell. They found that inhaled methyl iodide was retained from 53 per cent to 92 per cent, according to the tidal volume. Uptake by the blood was very rapid and metabolism was the same as for the iodide ion.

B. Altshuler, E. D. Palmes and N. Nelson used previous experimental data on total deposition of inhaled aerosol in man to calculate regional deposition. The method was to assume that part of the volume inhaled occupied the upper respiratory tract while the rest went into the alveolar spaces. The difference between measured total deposition and calculated upper tract deposition gives the lower tract figure. Deposition during inhalation, the respiratory pause and exhalation was calculated for the upper tract as if it were a continuous filter; allowance for mixing within the tidal air and between tidal air and residual air was based on data from previous wash-out experiments in which clean air was breathed after inhaling aerosol. The calculations were made for particles of diameter 0·14–3·2μ using a tidal volume of 500 cm^3 and

upper respiratory volumes of 100, 140 and 180 cm³. The results indicate that the diameter for maximal alveolar deposition exceeds 2μ, at which figure the alveolar deposition was between 20 per cent and 50 per cent, depending on the subject; the alveolar figure came out higher when the smaller upper respiratory volume was used. These curves for alveolar retention are at variance with previous work in that they suggest high alveolar deposition in the region of 3μ diameter.

E. D. Palmes, B. Altshuler and N. Nelson described experiments with an automatic apparatus for single-breath analysis. The human subject inhaled 625 cm³ of aerosol from a bag and exhaled twice this volume into another bag after a variable respiratory pause; the fraction of aerosol recovered decreased exponentially as the pause was lengthened.

Lung clearance in man was the subject of experimental work by P. E. Morrow and K. Gazioglu. Non-homogeneous radioactive aerosols were inhaled and the total deposition found by means of electrostatic precipitators. After washing out the mouth and pharynx the subject was measured in low-background surroundings by scintillation counters collimated to record both lung and tracheal activity. A continual decline in lung activity was observed, apart from two cases where a fluctuation was recorded in the first few hours. The validity of assuming a sequence of exponential decays is queried, but, on this basis, half-times of the order of 28 min, 80 min and 65 days could be deduced for an aerosol of manganese dioxide.

The sixth session was concerned with human lung dust. H. Leiteritz, H. J. Einbrodt and W. Klosterkötter reported extensive analysis of lung residues from coal-miners and compared them with the original mine dusts. Lung dust was separated by the formamide process and material from the Saar and Ruhr coalfields was examined. The quartz content of lung dust averaged 3–5 per cent and the peaks of the particle size distributions were in the 0·6–1·1μ diameter range for lung dust and more than 6·3μ, sometimes considerably, for mine dusts.

A discussion about the desirable size-selecting characteristics of sampling instruments in relation to the observed size frequency distribution of lung dust was presented by J. Cartwright. The average of many analyses of lung dust gave a mass frequency curve with a peak at 1μ diameter and 1 per cent of the peak value at 15μ. Selective sampling devices which accepted, on the basis of sedimentation rate, 50 per cent of the 5μ diameter particles and none greater than 7·1μ, would reject some 15 per cent by mass of the average lung dust in particles greater than 7·1μ, although the number of large particles in lung dust was very small. At the same time there was a great discrepancy between the number distribution curve of particle size in lung dust compared with that of the above-mentioned sampler, which collected a much greater proportion of the coarser particles in diameters up to 7·1μ. The net effects of these opposing tendencies was that the size-selected sample contained much more dust per unit volume of air than the lung residue and it had a completely different size distribution. In spite of these discrepancies, it was claimed, in this paper, that the relationship of sample weight to lung dust weight was not very sensitive to the variations of size distribution of airborne dust which are found in British coal-mines. The continued use of the demonstrably incorrect size selection was justified on the grounds that modification towards the true lung distribution would have caused inconveniently small samples to be collected, using the current times of sampling.

W. Stober, H. J. Einbrodt and W. Klosterkötter argued that, unless the elimination mechanism failed, it would be impossible for the quantity of dust retained in the lung to exceed a certain limit during exposure for an indefinite period. The equation which predicts this limit is in agreement with the results of animal experiments. Data from human lung residues were more uncertain, although there was some indication of the same pattern of retention. Human lung clearance appeared to be much slower than that of rats. There are indications that the human alveolar clearance mechanism breaks down after a certain dust load is attained, so that there is a marked increase in the rate of accumulation of lung dust.

The relationship between the chest X-ray picture and lung dust was the subject of a paper by C. E. Rossiter, D. Rivers and associates. A multiple regression analysis of likely factors led to the conclusion that the iron content of the lung was the best index of radiological category; the source and anatomical situation of this iron remain to be discovered.

L. Ulrich and A. Juck described analyses of the lungs of silicotic miners and noted that retention of fine particles apparently increases with size reduction, though it may be obscured by the relatively low frequency of occurrence of particles below 0·1μ in airborne dusts.

Four papers followed on the dose-response relationship in pneumoconiosis. Problems encountered in the Pneumoconiosis Field Research of the National Coal Board were explained by S. Rae. Evaluations of response by X-ray, pulmonary function or respiratory symptoms each have attendant difficulties; it is considered that the standardization of lung function tests is associated with less-severe drawbacks than the attainment of consistent X-ray pictures. Respiratory symptoms require, for their elucidation, a knowledge of the contribution of inhaled coal dust to chronic bronchitis.

D. G. Beadle spoke of silicosis in the South African goldfields. Groups of men engaged in eleven different occupations were examined and the associated dust exposures were evaluated. An average dust-level of 1,280 particles per cm³ was associated with 36 per cent certifications of silicosis after working 7,500 shifts and 700 particles per cm³ with 17 per cent certifications.

Routine recording of the monthly dust exposures of each miner in the West German coalmines made it possible for M. T. R. Reisner to show that the first pulmonary changes occurred earlier when the cumulative dust exposure was greater and the average dirt content of the respirable dust was lower. High dirt content delayed the onset of pulmonary changes within 7 years, possibly on account of a beneficial action of clay which has been shown in animals. The effect of peak concentrations over and above the integrated dosage is thought to be slight.

Another paper from the National Coal Board by J. M. Rogan, S. Rae and W. H. Walton reviewed the progress of the Pneumoconiosis Field Research which covers twenty-five selected collieries. A broad correlation has been found between the prevalence of pneumoconiosis and its progression, but the relationship of pneumoconiosis to dust concentration is vague, with some indication that certain collieries have more innocuous dust than others.

The practical difficulties associated with dust sampling by thermal precipitator have caused gravimetric sampling instruments to be regarded favourably, especially as the category of pneumoconiosis appears to be related to the weight and composition of the dust inhaled. It is hoped that gravimetric sampling will be more objective than particle counting. It is satisfactory that the prevalence of pneumoconiosis in British coal-mines has been materially reduced in the past five years, especially in the younger age groups.

H. E. Ayer and J. R. Lynch distinguished between motes and fibres of asbestos dust in the air of industrial plants. Most particles are motes, which resemble other industrial dust, but the proportion of fibres increases as the processing of raw asbestos advances. The health risk of asbestos dust is due to fibres, but whether the few long fibres are alone involved, or the more common fibres, 2–3μ in length, are important, has not been decided. Good indexes of exposure could be obtained by counting the concentration

of fibres using phase contrast microscopy or by using X-ray diffraction analysis.

A small cyclone size-separator was described by H. Breuer. This prevents coarse dust from reaching a sample collected on a filter and thus the size distribution matches that of dusts recovered from the lungs of coal-miners. The dust admitted to the filter is about 50 per cent of the airborne dust at 1·5μ diameter, rising to 80 per cent at 1μ; the acceptance curve is concave upwards and has, like the alveolar regions of the human lung, a small but definite acceptance beyond 7μ. The performance is insensitive to differences between quartz, coal and shale dusts.

The relationship between concentrations measured by mass and those measured by number was discussed by R. J. Hamilton, G. D. Morgan and W. H. Walton. The ratio of mass concentration (mg/m³) (measured after size selection by sedimentation with 50 per cent penetration to the sample at 5μ diameter), to number concentration, in thousands of particles more than 1μ diameter per cm³, ranged from 6 to 33; the spread was diminished when the size selection was made more rigorous, with a 50 per cent cut at 3·5μ, and this decreased the amount of dust collected by one-half to one-quarter. When the Breuer cyclone, described in the preceding paper, was used, the selected dust was about one-quarter that passing through the sedimentation instrument, which allowed a 50 per cent penetration at 5μ. Various gravimetric sampling devices agreed with one another within about 10 per cent.

In another paper, H. Breuer described measurements of size distribution of airborne coal-mine dust. The peak size frequency of dust during coal-getting occurs between 4μ and 8μ for coal dust, below 3μ for dirt and between 2μ and 6μ for quartz. The finer dusts, rich in dirt, are associated with pneumatic stowing and blasting. The composition of the fine, or respirable, fraction of dust depends on the method of selection.

W. Walkenhorst emphasized that, since knowledge of alveolar deposition of dust is so uncertain, it is desirable to analyse the composition of a series of fractions of dust in size ranges below 10μ, rather than taking a single arbitrary fraction of so-called respirable dust. He described a sedimentation classifier which distributed the particles, according to size, on a membrane filter. This allows analysis by optical microscopy, with determination of quartz content, in fractions down to 1μ.

The advantages of a personal dust sampler were stressed by R. I. Higgins and P. Dewell, who had made a small apparatus with a chest harness which weighed only 1·5 kg. Size selection was achieved by a cyclone with 50 per cent penetration for particles a little below 5μ in diameter, for density spheres, the sample being collected on a filter. Motive power was derived from rechargeable nickel–cadmium cells and an electric motor driving a diaphragm pump equipped with a pulsation damper.

The *Proceedings* of the symposium will again be published by Pergamon Press as a book; it is hoped that this will appear in June. C. N. Davies

CLEAN AIR

CLEAN air, in the true sense of these words, does not imply simply smokeless air; there is very much more to it than this. There are other aggressive agents of air pollution the control and ultimate elimination of which are of as great importance to the health of the community as the elimination of smoke, although the latter may often be the vehicle of their dissemination. These observations, and many other matters pertaining to the effects of the Clean Air Act and its impetus on progress in solving the problems of "the fog and filthy air", were well reviewed at the recent Clean Air Conference convened at Eastbourne during October 26–29, 1965, by the National Society for Clean Air. Pre-prints of papers presented at this Conference, together with summaries released at the time, are now available (Pp. 155. National Society for Clean Air, Field House, Breams Buildings, London, E.C.4, 1965. 15*s*.). The subject of smokeless air has been briefly discussed in these columns before (*Nature*, 204, 835; 1964); much has happened since then, particularly in respect to other hazards, notably sulphur dioxide, carbon monoxide, hydrocarbon exhaust fumes, grit and dust. In this connexion, a tightening up of the Clean Air Act (1956) would seem to be a practical possibility in the foreseeable future, particularly if coupled with the formulation of a sound national fuel policy, now receiving the attention of Mr. F. Lee, Minister of Power, according to *Smokeless Air* (35, No. 134; Summer 1965. Pp. 255. National Society for Clean Air. 2*s*. 6*d*.).

The presidential address to the Conference was delivered by Sir Alan Wilson. His main points were: a survey was carried out in fifteen pairs of housing estates of similar character except that one estate of each pair was subject to smoke control and the other was not; it was found that over 18 months, in the smoke-controlled areas, average concentration of smoke was 40 per cent less than in the areas not subject to smoke control (actual figures, 100 μg/m³ compared with 140 μg/m³). Although total smoke pollution had been considerably reduced, diminution in domestic smoke had been disappointingly slow; in London, however, during the period when the relevant air-pollution measurements were made (1952–62), smoke was reduced by about 60 per cent—much better than the national average of only 35 per cent. Against this, sulphur dioxide emission had increased in the London region by about 80 per cent as compared with slightly less than 25 per cent in Britain as a whole. Sir Alan explained this by the fact that much more sulphur dioxide was dispersed into the upper atmosphere through high chimneys than smoke produced near ground-level. He went on to say: "Since one ton of low-temperature coke contains only about 75–85 per cent of the sulphur in one ton of coal, and since 15 cwt. of coke produces as much heat as one ton of coal, replacement of coal by coke reduces the sulphur dioxide by about 40 per cent". Further, "Since there is no reasonable prospect . . . of reducing the total emission of sulphur dioxide throughout the country to negligible proportions, there is only one solution to the problem of smog, namely, town planning accompanied by the control of emissions by the regulation of fuel usage". This, of course, invokes the thorny problem of a national fuel policy with which, as already stated, the Ministry of Power is now grappling.

Most industrialized towns need not be dirty towns. This was the theme of three papers describing successes with smoke control. One of these is Manchester, the history of "some form of smoke control" of which extends over 120 years, according to Mr. J. Richards, senior public health inspector of that city. At the moment, 41·5 per cent of the total area of Manchester is subject to smoke control orders; it is hoped to make most of the city smokeless by 1970. Another city is Sheffield, discussed by Mr. J. W. Batey, chief smoke inspector; as a result of the City Council's efforts, air pollution measurements between 1956 and 1964 reveal that smoke nuisance has been halved and the amount of sulphur dioxide in the air considerably reduced. The third 'success story' is Scunthorpe, where Mr. G. O. Allen, chief public health inspector, stated that although the town had not reached

a "prosperous termination" of their desired end of air pollution, they were well on the way to their ultimate goal of "blue skies and pink lungs". Incidental to the problems faced is the question of solid fuel distribution and supplies; this was discussed by Mr. E. Otty, head of Special Projects Branch, National Coal Board, and Mr. W. H. Bourne, manager, National Federation of Coke Distributors' Associations.

One session of the Conference was devoted to the subject of air pollution and mortality. Mr. A. J. Wicken, head of Health Surveys, AGB Research, Ltd., stated that the findings of a recent survey in north-east England indicated that both lung cancer and bronchitis mortality are associated with air pollution. Speaking of odour control by catalytic combustion, Mr. E. Betz directed attention to the fact that many industrial effluents were not, as yet, covered by real legislation, it being left to local authorities to try to enforce production of clean and odour-free air; he claimed that, of available methods of removing organic fume nuisances, catalytic combustion was the most efficient; this could solve odour problems in the chemical industry, in nitric acid manufacture and in the oven industry among many other applications. The Belgian method for dealing with road vehicle pollution was described by Mr. E. J. Coucke, director, Fund for Study and Research on Road Safety, Brussels. This method is based on a closely integrated system of technical inspection of motor vehicles, involving fifty inspection stations, each equipped with a smoke-meter to measure diesel smoke density. Mr. Coucke went on to describe an interesting experiment designed to reduce rate of emission of carbon monoxide by petrol engines, which was conducted with vehicles used by the Paris Prefecture of Police; this is essentially a matter of precise adjustment of carburettors aimed at the systematic reduction of the production of this toxic gas while the motor is idling. His paper on Belgian practice in the matter of pollution of air by road vehicles is comprehensive and worthy of study.

It was perhaps inevitable that in such a Conference as this, new horizons in domestic heating should command attention, and the now familiar propaganda of what each of the competitive fuel industries has to offer in various heating systems, and what the domestic consumer in the United Kingdom may look forward to in the near future to realize efficient, economical and completely smoke-free warmth in the home, was characteristically conveyed by Mr. H. R. Brewster (Shell-Mex and B.P., Ltd.) representing oil interests; by Mr. R. N. Bruce (chairman, South Eastern Gas Board), concerned with gas (not excluding North Sea prospects); and by Dr. W. Reid (chairman, Northumberland and Durham Division, National Coal Board) in discussing steps being taken to promote higher standards of home heating apparatus, hence clean air, by production of adequate supplies of smokeless fuels, by stimulating design and production of new and, as near as possible, automatic appliances, and by district heating. The case for electricity was ably put by Mr. C. T. Melling (deputy chairman, the Electricity Council).

Mr. J. Hodgson spoke on industrial aspects of dust collection and selection of proper equipment to deal with the particular factory product or plant involved; his paper dealt, *inter alia*, with methods of settling chambers, inertial collectors (cyclones), fabric collectors, wet collectors and electrostatic precipitators. On the controversial subject of chimney heights, Mr. S. C. Beaumont (chief smoke inspector, Birmingham) referred to the *Memorandum of Chimney Heights* issued by the Ministry of Housing and Local Government which, although welcomed, did not provide all the answers to problems raised by conflicting interests in this matter, and which even the Clean Air Act failed to satisfy; he claimed that ". . . for reducing pollution from sulphur dioxide, tall chimneys apparently were the present answer, but the best remedy would be the use of low-sulphur content fuels". The Conference concluded by considering some unresolved problems in air pollution. In this connexion there was an important contribution by Mr. F. E. Ireland, chief alkali, etc., works inspector of England and Wales, who described some of the difficulties still with us concerning nuisances relating to sulphuric acid, nitric acid, ceramic industries, iron and steel, non-ferrous metals, metal recovery, and lime works; he added: "The search for solutions and improvements to industrial emissions continues unabated, both nationally and internationally".

The publicity afforded to the vital subject of clean air is in itself a healthy sign. The work of this Eastbourne Conference is a credit to all concerned. Britain is facing up to the problems involved in combating air pollution, from whatever source it may derive, and it is encouraging to know that so many other countries are doing the same. The first congress of the newly formed International Union of Air Pollution Prevention Associations will be held in London during October 3–7, 1966; some details of this desirable function are given in a recent number of *Smokeless Air* (36, No. 135; Autumn 1965. Pp. 13, 18. London: National Society for Clean Air. 3*s*.).

REACTIVITY OF PHOTO-EXCITED ORGANIC MOLECULES

THE Solvay Institute for Chemistry was founded in 1913, at a time when international conferences in science were comparatively rare. Since that time, as with other aspects of the rising tide of scientific knowledge, methods of communication have become much more numerous. Discussion meetings, conferences and symposia are being organized all over the world, to promote the advancement of knowledge on broad or narrow fronts of science. At the present time, those who are concerned with such organizing have to decide a number of questions, which it is useful to keep in mind when considering the outcome of any meeting of more than purely local appeal. When the primary object is to bring together and integrate related advances in different directions, as has always been the aim of Solvay conferences, the timing of the meeting, and the choice of those eligible to attend it, need to be planned with much greater care than is needed for more omnibus gatherings, at which the main object is to promote binary and ternary collisions of minds more or less at random, but in a favourable environment. If an integrating theme is aimed at, its selection must now also pay some regard to any related discussions at an international level, held or due to be held over a period which may extend over several years. Finally, the decision whether to publish *Proceedings* of a conference, to be of real service to a much wider circle of readers than those who actually attended it, calls for responsible judgment. This may not be easy, in view of the flood of scientific literature already available.

In the broad range of possible kinds of conferences, the pattern chosen by the Solvay Institute is one of the highest selectiveness in the choice of those invited to take part in the week's discussions. Only one or two pre-printed contributions were considered each day. In the present instance these were by C. A. Coulson, R. Daudel, G. S. Hammond, E. Havinga, G. Porter, G. O. Schenk, G. M. J. Schmidt and N. C. Yang. The printed texts were not restricted in length, in order to

permit each author to indicate the present problems of his own speciality, on an extensive perimeter. In addition to the authors and the members of the Scientific Council of the Solvay Institute, a limited number of leading scientists concerned with this field were also invited to attend. On this rather exclusive basis, those present found it feasible to discuss and define their difficulties, as well as to communicate their progress, without undue pressure from other speakers more anxious to communicate, than to attempt in common any Socratic assessment of ignorance. As in the case of other recent meetings of the Solvay Institute, on inorganic structural chemistry (1956), on nucleoproteins (1959) and on energy transfer in gases (1962), the invited papers and considered discussion contributions resulting from the compact team-work of the present meeting will be published in full, as soon as possible.

At this meeting some highly suggestive theoretical considerations about photo-excited molecules attracted much discussion. Advances in theoretical chemistry indicate that interactions between excited molecules may differ markedly from the situation described by the more familiar force fields and potential energy surfaces for molecules in the ground state. Compared with these, even the analogues of van der Waals' forces are likely to be of considerably longer range between excited species. In a molecular encounter, at the stage near what would be the transition state for unexcited molecules, more intense interactions likewise call for profound modifications in their description when they refer to electronically excited species. A general enlargement of the 'molecule volume' may be anticipated, within which the distribution of electronic charge can affect the course of chemical reaction between excited species.

This general inference points to a number of novel directions for theoretical and experimental research. Quite generally, even when apparently non-bonded, the influence of neighbouring molecules on a specific molecular reaction can be much more profound, when this involves photo-excited species, than for molecules in the ground state. A particular instance of the controlling influence of neighbours, which was extensively discussed at the meeting, but for which there still remains much to be clarified, refers to photo-chemical reactions in the crystalline state, or in solid solution.

Striking solvent effects on reactions between excited molecules may be closely related to this general principle, and several instances were discussed. Again, effects of pressure in determining the relative role of alternative chemical reactions should be much more prominent and distinctive, in favourable cases, than can normally be expected for reactions in the ground state.

The complexity of molecules the photo-chemical reactions of which can now be studied experimentally has increased in recent years to a notable extent, through the development of new methods of photo-excitation, and the use of various refined methods of chemical identification of the products. This has given new impetus to highly suggestive researches on problems such as the transmission of excitation energy within a polyatomic molecule, resulting from primary absorption of photons, or from irradiation by γ-rays or particles. Regions of a photo-excited molecule that may undergo quite diverse reaction can be examined on a selective basis. In addition to the great scientific interest of researches in this general direction, the technological mastery of economic production by photo-chemical means of quite complex molecules offers suggestive possibilities; though these were not discussed at any length at the meeting, they seem likely to attract more attention to this field in the future.

Calculations of the distribution of electron densities in molecules in their ground state can now be made with considerable confidence in favourable instances. However, there was some discussion about the extent to which such density distribution can guide assessments of reactivity of excited states. Novel ideas about charge transfer between excited molecules, put forward at the meeting by R. S. Mulliken, provided further fascinating glimpses of important future work in a field which promises to grow rapidly.

A. R. UBBELOHDE

SCHISTOSOMIASIS

MALARIA has been aptly called 'public enemy No. 1' and the title 'public enemy No. 2' might well be given to schistosomiasis, a lingering and often fatal disease of man and other animals including farm stock. The disease is caused by parasitic trematode flatworms belonging to the genus *Schistosoma* or *Bilharzia*. The latter name commemorates Dr. Bilharz, who first discovered the eggs of the parasite in Egypt and who was a pioneer in research on this trematode and on the disease it causes. Species of this genus, unlike other parasitic trematodes, are unisexual and live, not in the digestive tracts of their hosts as do many parasitic trematodes, but in the blood vessels: for this reason they are often called 'blood flukes'.

It is indeed good news that the Rockefeller Foundation, continuing its policy, so fruitful in the past, of giving financial aid to studies of the grave diseases that plague the world, has decided to undertake field investigations of schistosomiasis. The Foundation has been interested in schistosomiasis for 40 years. These investigations will be carried out on the small island of Santa Lucia in the Windward Islands; the Government of the Islands has also decided to give financial aid to these investigations. Schistosomiasis causes incalculable suffering and economic loss. It is estimated that some two hundred million people suffer from it in Egypt, Africa, South America, the Caribbean Islands, India and the Near and Far East. It has crippled large human populations and also agricultural progress, for some species of these trematodes infect farm stock. Egypt has been called the 'cradle' of the disease, because formerly it was prevalent there (the eggs of these trematodes have been found in Egyptian mummies dating from 1,000 B.C.).

Schistosomiasis is a disease that especially affects agricultural peoples who work on irrigated land or irrigation systems. Man is infected by larval forms of the trematodes (cercariae) which develop in certain species of aquatic snails living in streams, ponds, lakes and irrigation systems in which he may work or bathe. The cercariae are able to penetrate human skin and enter the blood stream, which carries them to the blood vessels of the abdomen. Here they settle down and become sexually mature and lay spined eggs which work their way out of the infected person through the wall of the intestine or bladder into the faeces or urine. In so doing they cause bleeding from, and other forms of damage to, the walls of the bladder or intestine. Human faeces and urine contaminated with the eggs of the trematodes are frequently discharged into local waters. The eggs liberate larvae into the water which penetrate into snails living under water and develop inside the snails into cercarial larvae which leave the snails and can subsequently infect man.

It will be clear, therefore, that the disease is, in this sense, man-made.

Control of the disease aims at: (1) Protection of the human skin from the cercariae by wearing suitable clothing or by avoiding infected waters. (2) Destruction of the species of snails involved by means of chemical sub-

stances (molluscicides) and by measures which will make the environments of the snails unfavourable (clearing of vegetation, etc.). (3) Education of the people in the life-history of the parasite and the mode of infection, and in the need for better methods of disposal of their excreta.

Much research is needed on molluscicides and on methods of applying them, and on the habits and biology of the species of snail involved. Investigation of methods of treating infected people and on drugs suitable for this purpose is also necessary. Unfortunately the drugs so far discovered that will kill the adult trematodes in the blood vessels are compounds of arsenic or antimony, which may have serious effects on the patients treated with them. The World Health Organization* is also sponsoring work on this disease, and Prof. George Macdonald has given up his directorship of the Ross Institute of the London School of Tropical Medicine and Hygiene to lead a team based at Makerere Medical School, Kampala, Nigeria, which will work on schistosomiasis. In 1961 the Rockefeller Foundation gave a grant of 142,500 dollars to aid this work. The team will work in co-operation with the staff of the East African Medical Research Council on the disease in Africans in the area of Lake Victoria.

HYDATID DISEASE

A NUMBER of publications recently issued by the National Hydatids Council of New Zealand will be of interest to anyone concerned with public health.

One of these, entitled *Hydatid Disease in New Zealand**, describes the events which led to the establishment of the National Hydatids Council. It gives statistics about the prevalence of the hydatid tapeworm in New Zealand dogs and the incidence of hydatid cysts, which are the larval (bladderworm) stages of this tapeworm, in cattle, sheep, pigs and man, together with figures of the incidence of the cysts of another tapeworm of the dog, *Taenia hydatigena*. It has been estimated that hydatid disease is more common in New Zealand than in any other country, and that as a cause of death it is three times more prevalent in New Zealand than in Australia and twenty times more than in England and Wales. It is five times more prevalent in Maoris than in Europeans, and at the present time more than 20,000 New Zealanders may be infected with hydatid cysts. This is ascribed to the fact that the range and degree of moisture in New Zealand favour the survival of the eggs of the tapeworm after they have been passed out of the dog in its excreta. Pertinent is the fact that New Zealand farmers feed their dogs on uncooked offal containing the hydatid cysts, from which the adult tapeworms develop in the food canal of the dog. The pamphlet also describes early and subsequent attempts at control of the infection in man. It discusses methods of educating the public in the ways in which infection with hydatid cysts may be acquired, spread of knowledge of this kind and its effects, the general awakening of public conscience about the disease, and the formation of the National Hydatids Council.

The function of the Council is to exercise central control of measures used for the eradication of the tapeworm and of the disease caused by its hydatid cysts. It is now an offence to fail to register a dog or to bring it to one of the control centres for dosing with a drug that will kill the tapeworm. Furthermore, it is illegal to feed a dog on raw offal or to allow it to have access to such. As a result, the infection of dogs with the hydatid tapeworm has been reduced in about seven-eighths of New Zealand to 2 per cent, and in half the country to 1 per cent or less. Control of *T. hydatigena* has been less satisfactory, but there has been a considerable reduction of the rate of infection of dogs with this species. It is, however, hoped that it will be controlled by the measures taken to eradicate *E. granulosus*—the life histories of these two species being similar.

Further information about the work of the National Hydatids Council is given in the fifth annual report and statement of accounts of the Council for the year ended March 31, 1965†. The Council has also issued a valuable pamphlet entitled *Hydatids Eradication in Iceland*‡, which describes the remarkable achievement of that country, in which, during 1860–70, some 15,000–20,000 dogs heavily infected with *E. granulosus* were kept by a total population of 70,000 people, most of whom were sheep farmers living under relatively primitive conditions. In 1840 the Chief Medical Officer estimated that one person in every seven was infected with hydatid cysts. Later evidence showed that one in every four or five was infected. Methods used to control the disease included: (1) education of the public in the life history of the tapeworm and the parts played in it by man, dog and sheep; (2) taxation of dogs in order to limit their numbers—at present there is a tax of £7 10*s*. on each pet dog and 15*s*. on each working dog, and in some towns the local authorities are empowered to forbid the keeping of dogs; (3) compulsory annual treatment of all dogs with an anti-tapeworm drug at special centres; (4) enforcement of the law of 1890 forbidding the feeding of dogs on any entrails of sheep or cattle and enacting the deep burial or burning of the internal organs of sheep infected with hydatids; (5) improvements in the general hygiene of the people and in certain farm practices likely to favour the infection of man with the cysts.

A table demonstrates the dramatic decline in the incidence of human infections with hydatid cysts that followed these energetic measures. In 1904 it was possible to conclude that hydatid disease was practically extinct in Iceland and there was a corresponding decrease in the incidence of the cysts in sheep and also of the tapeworm dogs. Although *E. granulosus* and its hydatid cysts thus appear to have been eradicated from man in Iceland, *T. hydatigena* and its cysts in sheep have not been eradicated; however, their incidence has been reduced.

For readers who are not parasitologists but who require a clear and accurate account of the structure and life history of the hydatid tapeworm *E. granulosus*, the National Hydatids Council has issued a publication entitled *Parasitic Animals, with Special Reference to Hydatid Disease*§. It is well illustrated and gives an excellent account of the characteristics and life history of *E. granulosus*. Also dealt with are the relationship of this parasite with other tapeworms and the epidemiology of hydatid disease, its incidence in New Zealand and the measures designed to prevent this disease. Another table gives a comparison of the appearance, lengths and hosts of the seven species of tapeworms found in dogs in New Zealand.

INACTIVATION AND INDUCTION OF ELECTRON SPIN RESONANCE-CENTRES IN TRYPSIN BY IONIZING RADIATION AND BY ULTRA-VIOLET LIGHT

By TOR BRUSTAD

Norsk Hydro's Institute for Cancer Research, Montebello, Norway

IN an investigation of inactivation on RNase by cobalt-60 γ-rays, Hunt and Williams[1] correlated the yield of one class of radicals with the changes in the radiosensitivity of the enzyme irradiated in vacuum and in oxygen, and after post-irradiation treatment with oxygen. The rate of production of "sulphur-type" radicals was correlated with the yield of free SH-groups measured by titration.

Henriksen[2] has shown that the total yields of electron spin resonance (ESR) centres in trypsin, exposed at various temperatures to different types of radiation, parallel those for enzyme inactivation under the same conditions[3]. Similar investigations have not been conducted with non-ionizing ultra-violet light. However, Kock and Mönig[4] found that ESR-centres were induced in bovine serum albumin when exposed to ultra-violet light of wave-length 254 mμ, and furthermore, that the shape of the ESR-signal of centres induced by X-irradiation in this compound changed on subsequent exposure to ultra-violet light of wave-length exceeding 300 mμ, without concomitant change of the total number of radicals.

I have carried out investigations with the view of making a comparison between enzyme inactivation and the number of ESR-centres, induced by γ-rays and ultra-violet light separately.

Twice-crystallized trypsin was obtained from Worthington Biochemical Corporation, United States. About 10 mg was placed in each of a number of quartz tubes, evacuated for 24 h and sealed off under a vacuum of about 5×10^{-6} mm mercury. One set of samples was subjected to γ-rays from a 5,000 c. cobalt-60 therapy unit (type 'Gammatron 3'), manufactured by Siemens, Germany. The dose-rate was about $2{\cdot}5 \times 10^4$ rads/min and the temperature of the samples during irradiation was kept at 0° C.

Another set of samples was subjected to ultra-violet light from a medium pressure mercury lamp (type *UVS* 500) made by Engelhard Hanovia, England. Samples subjected to ultra-violet light were irradiated with the proteins evenly distributed in the tubes, and shaken every 3 min during the exposure, in order to obtain a more uniform dose distribution in the sample material. During the exposure to ultra-violet light, the tubes were kept immersed in distilled water at a temperature of approximately 10° C. After the exposure, the ESR-signals were determined in an X-band spectrometer with transmission cavity and 110-kc/s field modulation. The spectra are recorded after phase-sensitive detection and represent the first derivatives of the absorption curve. Before carrying out the analysis in the ESR-spectrometer, the sample material was transferred to one end of the quartz tube and immersed in liquid nitrogen while the other end of the tube was heated to eliminate the ESR-centres in the quartz tube itself. The number of ESR-centres was obtained by double integration of the spectra and comparison with diphenylpicrylhydrazyl (DPPH) standards, according to the method described by Henriksen[5]. After completion of the ESR-analysis, the tubes were broken in air and enzyme activity determined according to the method described by Schwert and Takenaka[6].

It is seen in Fig. 1 that the dose-effect curves are exponential when trypsin is subjected to γ-rays, but this is not so when exposed to ultra-violet light. This is probably due to heterogeneous dose distribution within the sample material in the latter case.

It is seen in Fig. 2 that the shape of the ESR-spectrum of radicals induced by ultra-violet light has many features in common with that of the γ-ray-induced centres. The peaks in the spectra occur at the same magnetic field strengths, but they appear to be somewhat better resolved in the latter case.

Fig. 3 shows that there is a linear relationship between the number of ESR-centres induced by ultra-violet light and the corresponding inactivation, throughout the inactivation range studied. When exposed to γ-rays, on the other hand, the number of radicals per gram increases rapidly with increasing inactivation, but it would seem that a saturation is approached after prolonged exposure. Since the molecular weight of trypsin is about 23,000, the saturation value corresponds on the average to slightly less than one spin per enzyme molecule. Thus, the spins induced by ionizing radiation have a different dose-dependence from the inactivation. There may be an approximate linear relationship between the number of spins per gram and the corresponding inactivation when the latter is very small, as indicated by the dashed line in Fig. 3. Of particular importance is the fact that within the linear portions of the curves shown in Fig. 3, approximately five molecules are inactivated per spin induced by ultra-violet light, whereas only 0·25 molecules are

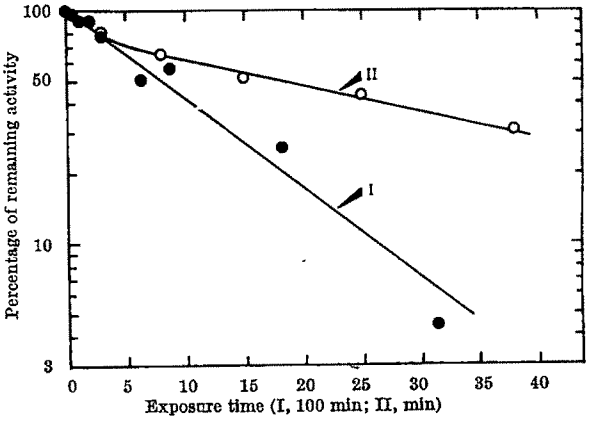

Fig. 1. Dose-effect curves of trypsin exposed to: I, cobalt-60 γ-rays; II, ultra-violet light

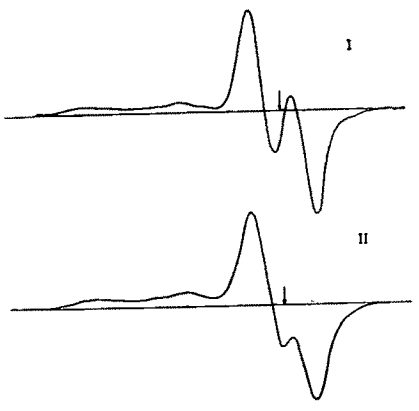

Fig. 2. Electron spin resonance spectra of trypsin irradiated with. I, cobalt-60 γ-rays; II, ultra-violet light. The arrow indicates the position of the DPPH signal

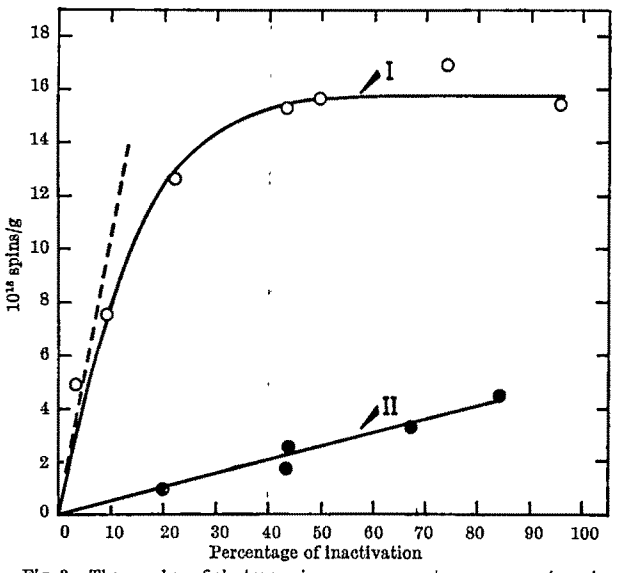

Fig 3. The number of electron spin resonance centres per gram trypsin as a function of the degree of injury, expressed as per cent inactivations: I, cobalt-60 γ-rays; II, ultra-violet light

inactivated per spin induced by γ-irradiation. This indicates that the ESR-centres induced by ultra-violet light and γ-irradiation play different parts in the processes leading to enzyme inactivation. It is possible, however, that enzyme inactivation may be induced by ultra-violet light of certain wave-lengths without simultaneous induction of spins, and/or that the spins detected at room temperature merely represent a late step in a long chain of reactions initiated by the primary absorption event, and that the inactivation is related to an earlier step in this sequence of events.

In the present investigation it has been shown that ESR-centres are induced in dry trypsin by ultra-violet light. Although the shape of the ESR-signal induced by ultra-violet light resembles that induced by ionizing radiation, it is important to note that they are not identical. A linear relationship was found between the number of spins induced by ultra-violet light and the degree of inactivation. A similar relationship does not seem to hold for ionizing radiation, except when the inactivation is quite small, where the injury per spin induced by ultra-violet light may exceed that per spin induced by γ-irradiation by more than an order of magnitude. The number of observed γ-induced radicals (X) increases with the exposure time (t) in a manner which may be described by the kinetic equation:

$$\frac{dX}{dt} = I - kX^2$$

$$X = \sqrt{\frac{I}{k}} \tanh \sqrt{kI}\, t$$

where I is the number of radicals induced per unit time by the radiation and k is the rate constant for reaction between two radicals. The present findings may have a bearing on the question of the relative roles of ionization and excitation processes in the radiation inactivation of enzymes[7].

I thank the Norwegian Cancer Society for grants, and Nansenfondet and Stangs Legat for technical equipment.

CEMENTED FORAMINIFERAL OOZES FROM THE MID-ATLANTIC RIDGE

By Dr. RICHARD CIFELLI
U.S. National Museum

Dr. VAUGHAN T. BOWEN
Woods Hole Oceanographic Institution

AND

Prof. RAYMOND SIEVER
Harvard University, Cambridge, Massachusetts

DURING a recent investigation[1] of the mid-Atlantic Ridge about 22° N., several pieces of late Tertiary foraminiferal limestone were recovered. These represent at least two and probably three distinct ages, indicated by their assemblages of planktonic Foraminifera. The oldest is probably late Miocene, correlative with the assemblage associated with basalt dredged in this same area[2] on an earlier cruise. Another assemblage is somewhat younger, probably early Pliocene, and a third is possibly still younger, approaching middle Pliocene.

The present collection of cemented oozes came from a peak on the western flank of the Ridge. Several pieces of dry, buff-coloured cemented ooze, showing only traces of manganiferous coating, were collected in a free corer[3] dropped on top of the peak, at 3,000 m depth. Although the core liner was filled to 10 cm with lumps of ooze, it contained no unconsolidated material, suggesting that the cemented ooze was here exposed on the sea floor. Although there were no apparent differences among the pieces, they were individually labelled and several examined separately, in an effort to discern a stratigraphical sequence.

Three other distinct pieces were obtained in a pipe dredge, dragged from 3,300 m to almost 3,100 m depth, up the southern slope of the same peak: *Dr* 10–*P*1—a lump of cemented ooze; *Dr* 10–*P*2—a lump of cemented ooze with many inclusions of orange altered palagonite; and *Dr* 10–*P*3—a chip of fresh basalt, coated on one side with cemented ooze. Each of these pieces showed a heavy manganiferous coating. The Foraminifera from each piece were examined separately.

The species assemblages of the various samples, and the ages assigned, are shown in Table 1. The fact that all the samples are late Tertiary can confidently be established, as can be most of the relative ages; there may be some question whether the *FC* 24 samples are certainly younger than *Dr* 10–*P*1. The relative age determinations have been based on the succession of planktonic Foraminifera established for the Caribbean[4,5], and on the recently proposed Neogene zonation of Blow and Banner[6]. Considerable uncertainty still exists, however, as to how these foraminiferal successions correlate with the standard European Stages and Series boundaries. Therefore, we use here the terms late Miocene, lower Pliocene and middle Pliocene as units of convenience; these provisional age designations can be adjusted later if necessary.

The oldest samples, *Dr* 10–*P*2 and *Dr* 10–*P*3, contain similar assemblages and are essentially contemporaneous. They are correlative with the cemented ooze previously dredged in the vicinity and, therefore, are late Tertiary, probably late Miocene, in age[2]. Diagnostic species include: *Sphaeroidinella seminulina, Globoquadrina dehiscens, G. altispira, Globigerina nepenthes, Globorotalia*

miocenica and *G. tumida sensu lato*. Although the ranges of these species are not yet completely established in the published literature, their association indicates an age within the *Sphaeroidinella seminulina* zone of Blow[5] and Zone *N*-18 of Blow and Banner[6]. As proposed, both these zones are believed to represent latest Miocene[5,7].

Specimens referred to here as *Globorotalia miocenica* and *G. tumida sensu lato* are identical with those previously designated *G. fohsi robusta*[2]. This change is based on the recent revision and clarification of the *G. fohsi* and *G. tumida* groups[7,8].

The *Globigerinoides bisphaericus* group homoeomorphs include specimens which, in general form and chamber arrangement, are indistinguishable from *G. bisphaericus*, *G. glomerosus*-and *G. transitorius*, parts of a lineage that provide important index markers in the middle Tertiary. According to W. H. Blow (personal communication), however, our mid-Atlantic Ridge specimens can be distinguished by their lack of slit-like apertures, and usually less deeply incised sutures. Such forms, apparently, are not uncommon in late Tertiary samples (Blow, personal communication); therefore, their occurrences here are stratigraphically compatible with the rest of the assemblage.

Dr 10–*P*1 is characterized by a younger assemblage, although having much in common with the preceding samples, including *Globigerina nepenthes*. Absent here, however, are *Globoquadrina dehiscens*, *G. altispira* and *Sphaeroidinella seminulina*. All the *Sphaeroidinella* in *Dr* 10–*P*1 have well-developed secondary apertures and are referable to *S. dehiscens*, a species that is younger, and descendant from *S. seminulina*. Also occurring in *Dr* 10–*P*1, indicating an age younger than *Dr* 10–*P*2 and *Dr* 10–*P*3, is a keeled form of *Globorotalia punctulata*.

The *FC* 24 samples differ from *Dr* 10–*P*1 mainly in the absence of *Globigerina nepenthes*. Replacing this species is the similar, but distinct form, *G. decoraperta*. The records[9] of *G. decoraperta* thus far are from Japan, where it is associated with and ranges higher than *G. nepenthes*; thus, the presence of *G. decoraperta* along with the absence of *G. nepenthes* is suggestive of a younger age for the *FC* 24 samples.

We are aware of four additional recoveries of cemented ooze from dredges elsewhere on the Ridge. Two of these, one from the east slope of the central valley floor (45° 44′ N., 27° 43′ W.) and one from a peak near the central valley (46° 51′ N., 27° 39′ W.), consisted of several cobbles of "foraminiferal limestone"[10]. No reports of the other two recoveries have been published. One (Case 3) was dredged at 36° 31·5′ N., 33° 34′ W. between 1,800 and 1,650 m depth, on the south side at the top of a ridge on the south side of the median valley. The other (Case 4) consisted of specimens dredged at 42° 39′ N., 28° 59′ W. about 1,700 m deep and at 42° 41′ N., 28° 02′ W. about 1,850 m deep; these dredges are described (Chase, personal communication) as having been on opposite sides of a north-trending ridge that here forms the eastern side of the median valley. In each case the Foraminifera have been examined (cases 1, 2—Funnel, personal communication; cases 3, 4—Todd, personal communication) and assigned to typical Quaternary assemblages.

Case 1, 2—Funnel, personal communication; cases 3, 4—Todd, personal communication.

In assessing the significance of these cemented oozes and of their relative ages, it is important to have a hypothesis of the mechanism of consolidation. Although it is frequently assumed that the only mechanisms available require sub-aerial exposure, this is not geologically correct; in the case of the mid-Atlantic Ridge dredges, such exposure seems very improbable. One alternative has recently been described[2] in the form of silicic cementation noted in material dredged from a valley near the location of the collections described here; this silicic cementation was postulated as resulting from volcanism in the area.

More generally, the sort of slight cementation with calcium carbonate, observed in the cases noted here, may be expected to result simply from uplift of an ooze to a depth 2,000 m or so less than that at which its interstitial water had become equilibrated. The sedimentological and geochemical evidence for high-pressure dissolution of carbonate sediments has recently been summarized[11]. The physical chemistry of calcium carbonate dissolution in the interstitial waters of deep ocean sediments is not yet well understood. Analytical data on such solutions[12], together with recent investigations of the effects of pressure[13] and temperature[14] on calcium carbonate solubility, allow us to estimate that in an ooze initially close to equilibrium with its interstitial water, the reduction in hydrostatic pressure and increase in temperature consequent on uplifting by about 2,000 m would permit local reprecipitation of as much as 200 mg calcite per litre of sediment. Such an amount seems not unreasonable to provide the very friable aggregations of ooze observed. As Siever[12] has summarized, saturometer[15] measurements on surface sea water everywhere show super-saturation with calcite; by contrast, interstitial waters, even when expressed from foraminiferal oozes of considerable palaeontological age, are very frequently undersaturated. Siever suggested[12] that the waters are, in fact, in equilibrium, and that the observations may indicate that the low-magnesium calcite of foraminiferal tests is less soluble than the reagent-grade calcite used in the saturometer as standard. Lacking conclusive evidence, it seems to us best to accept the sedimentological evidence for the low-temperature, high-pressure dissolution of foraminiferal oozes, and consequent reprecipitation when uplifted.

Other hypotheses may be considered: one is that the spectrum of biogenic carbonates reaching the ocean floor ranges from low-solubility, low-magnesium calcites to high-solubility, high-magnesium calcites[16], and that as the solution of the latter supersaturates interstitial waters with respect to the former, cementation occurs by grain-growth at the margins of the low-solubility tests. Such a mechanism, we believe, would result in relatively rapid cementation of oozes buried anywhere on the ocean floor; in fact, as shown by the relative infrequency of their finding, cemented oozes are not common in marine sediments, even when high rates of sedimentation would appear to favour their production. Analytical data[17] have shown consistently low magnesium content for the tests of planktonic Foraminifera. The depletion in magnesium generally shown by interstitial waters[12] also argues against

this mechanism. Finally, work in progress on the mineralogy of oozes from the mid-Atlantic Ridge in the area about 23° N. has consistently shown a well-crystallized calcite with only one mole per cent $MgCO_3$ in solid solution.

Similar arguments seem to obtain against alternative precipitations of silica or carbonate in low or high *p*H regions of a sediment[18]; if operative, this should give local cementation rather commonly in oozes; also, considering the relative abundances in plankton of siliceous and carbonate skeletons[19], silica cementation should be roughly as common as is calcitic, whereas the former appears much rarer. The one case of siliceous cementation we have observed[2] presents a combination of silica and calcite cement which could not be produced by the mechanism proposed.

We therefore still consider, then, that mixed calcite–silica cementation offers an indication of volcanism, and that the so far more typical purely carbonate cementation of oozes indicates uplift, after a significant equilibration time at water depths of 5,000 m or more. On this basis, it seems of real interest that foraminiferal limestones of Tertiary age have been recovered on the flanks of the Ridge, from relief argued[1] from other evidence to be relatively old, whereas similar rocks but of recent age have repeatedly been collected near the crest of the Ridge, from relief which appears from other evidence[1] to be much younger. It is equally interesting that in the one case where, even marginally, an age-progression can be suggested (*Dr* 10), the older limestones are those associated with the basalt surface. Should the hypothesis posed here prove generally useful, palaeontological dating of cemented oozes would provide a valuable way of setting limits to the timing of tectonic processes in the deep ocean. Careful search for other occurrences of this sort is an important part of our planning for forthcoming cruises; we urge its importance on our colleagues.

This work was supported at sea and at the Woods Hole Oceanographic Institution by the U.S. Atomic Energy Commission under contracts *AT*(30–1)–2174 and *AT*(30–1)–3010; by the U.S. Office of Naval Research under contract *Nonr*-2196 (00); and by the U.S. National Science Foundation under grants *GP* 921 and *GP* 1599. We thank the officers, crew and scientific party of the R. V. *Chain* for their assistance. We also thank various of our colleagues, especially Dr. Walter H. Blow, British Petroleum, Ltd., for their advice and assistance.

STRAIN IN CRYSTALS DETECTED BY X-RAY

By J. E. GILLOTT and P. J. SEREDA
Division of Building Research, National Research Council, Ottawa, Canada

IT is useful to know whether the crystals forming a rigid polycrystalline body are strained, especially when such bodies are formed by compaction of the powdered microcrystalline material at moderate pressures. Residual internal stress in the crystals may have an influence on its mechanical properties, particularly its stability, when subjected to cyclical conditions.

X-ray diffraction transmission Laue photographs of deformed polycrystalline materials often show asterism, the radial distortion of the spots[1,2]. This article discusses the use of this technique to detect strains in samples of hydrated cement, $Ca(OH)_2$, and analytical reagent grade NaCl in the form of compacts, powders, and wafers.

In this technique, unfiltered copper X-radiation was employed and the diffraction patterns were recorded on film held either by a flat-plate holder mounted at a distance of 4 cm from the sample or by a cylindrical cassette of 5·73 cm diameter. The samples were also examined on the petrographic microscope.

A normal portland cement was used which was hydrated by two procedures. In the first the cement was hydrated essentially to completion in an excess of water by continuous rotation in a bottle on a wheel. The hydrated cement was recovered as a powder. In the second the cement was hydrated in the normal fashion as a paste with a water/cement ratio of 0·5 by weight.

Two varieties of $Ca(OH)_2$ were investigated. One variety formed as a hydration product of cement. When hydration was carried out in an excess of water the crystals reached a size of about 1 mm. They were separated by sieving from the hydrated cement powder. The second variety of $Ca(OH)_2$ crystals was grown by the diffusion technique of Johnston[3] using $CaCl_2$ and NaOH.

The compacts were made in a mould 1·25 in. in diameter and the quantity of powder was adjusted so that after compaction the sample had a thickness of 0·25–0·5 mm when pressures in the range of 5,000–100,000 lb./in.^{2} were employed. Some compacts of NaCl were annealed in a muffle furnace at a temperature of 500° C. Wafers of dimensions similar to the compacts were cut from a cylinder of normally hydrated cement by means of a diamond saw. Powder samples were gently pressed by hand into a flat-plate holder and held in place by admixture with a small quantity of gum.

Laue photographs obtained from wafers of the cement hydrated as a paste showed marked asterism (Fig. 1*a*). This was also present on Laue photographs of the compacted and uncompacted samples of cement powder hydrated in an excess of water. A Laue photograph of the uncompacted $Ca(OH)_2$ separated by sieving from the cement hydrated in an excess of water also showed asterism (Fig. 1*b*). The film was remarkably similar in appearance to that obtained from the cement powder hydrated in an excess of water, suggesting that in this case the observed diffraction effects resulted largely from the $Ca(OH)_2$ crystals. The radial distortion of spots was even more marked on a photograph obtained from this material after it had been compacted at 20,000 lb./in.^{2}. The powder sample of $Ca(OH)_2$ crystals grown by the slow diffusion process gave Laue photographs which showed very little asterism. Laue photographs of this material after compaction at 20,000 lb./in.^{2} showed a similar amount of asterism to that observed on films of the uncompacted $Ca(OH)_2$ separated from the cement powder by sieving. A single crystal of the $Ca(OH)_2$ separated from the hydrated cement powder showed distorted spots on

discontinuous Debye–Scherrer powder rings; Laue spots showed asterism.

The NaCl (reagent grade) uncompacted powder sample gave a Laue photograph which showed some asterism. Compaction at 800, 6,000 and 20,000 lb./in.^{2} was accompanied by a progressive increase in the amount of asterism shown on the Laue photographs. Annealing the compact for 1 h at 500° C removed a large amount of the asterism from the corresponding Laue photograph. Annealing for 42 h was required before the Laue photograph of the compact showed no asterism. There was only a very slow decrease with time in the amount of asterism present on Laue photographs of an NaCl compact conditioned in a desiccator held at 50 per cent relative humidity. This result is in accord with that of Lewis and Pearson[4], who studied X-ray diffraction-line broadening in the alkali halides.

X-ray photographs of the polycrystalline samples examined showed discontinuous Debye–Scherrer rings, but these were sometimes only visible in the back reflexion region. Their absence in the front reflexion region on some photographs was attributed to absorption in somewhat thicker or denser samples. Spots were commonly distorted around the circumference of the circle. After annealing the circumferential streaks on the photographs from the NaCl compacts were replaced by small sharp spots, the extent of the replacement depending on the length of annealing time. Photographs of the $Ca(OH)_2$ separated by sieving from the cement powder showed this effect though no attempt was made to anneal the sample. The Debye–Scherrer rings were generally more continuous on photographs of compacted samples than on photographs of uncompacted samples and the size of the spots was often reduced.

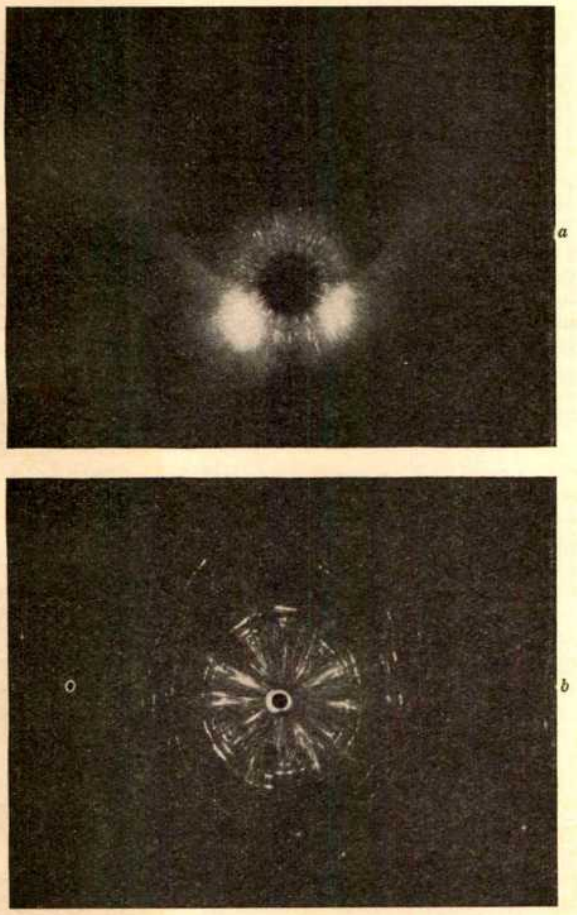

Fig. 1. X-ray diffraction photographs showing asterism. *a*, Cement wafer hydrated as a paste; *b*, $Ca(OH)_2$ sieved from cement hydrated in excess water

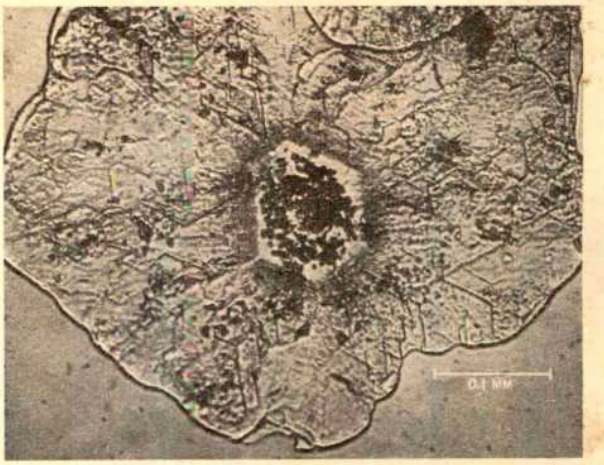

Fig. 2. Photomicrograph of oriented inclusions in $Ca(OH)_2$ separated from cement hydrated in excess water

Most of the samples were examined under low power magnification under the binocular and at higher magnification under the petrographic microscope. The $Ca(OH)_2$ crystals which grew as a product when the cement was hydrated in an excess of water were plate-like. Those grown by the diffusion technique of Johnston[3] were of different morphology. They were elongated normal to the base (0001) in the form of hexagonal prisms which were sometimes hollow. Differences in shape of $Ca(OH)_2$ crystals have been discussed by Hedin[5] in terms of differences in growth rate on different faces. He suggested that the presence of a very low concentration of impurities which absorb on growth steps such as screw dislocations may affect the growth mechanism[5]. He found that growth of prism faces began at a lower concentration of solution than did growth on the prism bases. Once growth had started, however, an increase in solution concentration caused a more rapid increase in growth rate on the basal surface than on the edges of the crystals. Predominant growth on basal surfaces favours long rod-like crystals whereas, if the growth is mainly on the edges, plates are produced. Differences in concentration between the $CaCl_2$-NaOH and hydrating cement system and much higher concentration in the latter of impurities with possible growth-interfering properties may have influenced the difference in morphology of the two types of $Ca(OH)_2$. The $Ca(OH)_2$ sieved out from the cement powder contained small inclusions symmetrically arranged in hexagonal form. Some of the inclusions within the hexagons appeared to show a spiral arrangement (Fig. 2). This is suggestive of rotation during growth and may result from a screw dislocation type of growth mechanism. Alternatively, the method of preparation may be responsible as this involves continuous rotation on a wheel. A few of the $Ca(OH)_2$ crystals contained randomly oriented lath-shaped inclusions of larger size than the symmetrical inclusions. The $Ca(OH)_2$ showed undulatory extinction on rotation of the microscope stage under crossed polars.

The classical interpretation of asterism is that it is due to diffraction from crystals in which the lattice is bent. Annealing removes the distortion and the diffraction streaks are replaced by sharp spots characteristic of diffraction from an undeformed crystal. The separation of the streaks into a number of sharp spots is attributed to polygonization or the fragmentation of the larger distorted crystal into a number of well-defined sub-grains which differ slightly in orientation.

On the basis of this view it appears that there is distortion in the crystal lattice of the $Ca(OH)_2$ formed during hydration of cement in an excess of water. This conclusion is supported by the undulatory extinction observed under crossed polars on the petrographic microscope. The similar effects observed on the X-ray photographs of the

cement hydrated as a paste suggest that distorted $Ca(OH)_2$ was also formed during the paste hydration process. The polygonization in the separated unannealed crystals implies that partial recrystallization also took place when an excess of water was present. Very little lattice distortion was present in the crystals of $Ca(OH)_2$ grown by slow diffusion. Compaction resulted in deformation and a reduction in the size of the crystals. Similar conclusions apply to the results obtained with the NaCl powders and compacts.

The evidence of distortion in the crystal lattice leads to the conclusion that the crystal was subjected to some form of stress at some stage in its formation. This was certainly the case during compaction, but such stress is difficult to account for when crystals grow from solution in a free medium, as was the case for the $Ca(OH)_2$ formed by hydration of cement in a rotating bottle. The fact that inclusions were observed in the crystals of $Ca(OH)_2$ (Fig. 2) may account for the presence of strain. When cement hydrates as a paste it is acceptable to consider that stress is applied on the growing crystal, because the products must accommodate to the spaces formed by the structure of the unhydrated particles as well as to the primary hydration products.

The important question is whether distortion in crystals is evidence for the presence of residual internal stress. If so, one would anticipate that such crystals would be more reactive, might recrystallize (age) more readily, and would be less stable dimensionally especially under cyclical conditions of temperature or moisture change, than crystals of the same size having no residual internal stress.

Certainly in the case of NaCl, the lattice distortion tended to disappear after annealing, indicating that the distortion resulted from residual internal stress. Residual internal stress in crystals may have a significant influence on the mechanical properties of a rigid polycrystalline body.

NECROGENIC ACTION OF CARBON TETRACHLORIDE IN THE RAT: A SPECULATIVE MECHANISM BASED ON ACTIVATION

By Dr. T. F. SLATER
Department of Chemical Pathology, University College Hospital Medical School, London, W.C.1

'NECROSIS is the death of a group of cells as a result of injurious influences while still in contact with the living body[1].'' The group of cells may be very small in number or of grave and catastrophic proportions, as in acute yellow atrophy of the liver, where over 90 per cent of the parenchymal cells are destroyed.

Biochemical and histopathological studies aimed at a successful interpretation of the mechanisms culminating in necrosis have been legion. In general, attention has been concentrated on the response of experimental animals (in particular, the rat) to a relatively few poisonous substances which are readily available and which produce a consistent injury. One such substance studied *in extenso* has been carbon tetrachloride[2].

Administration of a suitable dose* (0·125 ml./100 g body-weight) of carbon tetrachloride to rats (and to many other species, though not to new-born rats or chickens) results in a severe centrilobular type of necrosis and fatty degeneration of the liver[3]. These processes induced by carbon tetrachloride, and which lead to necrosis on one hand, or to fatty accumulation on the other, appear to utilize different metabolic pathways which, to a large extent, can be dissociated from one another, at least in their terminal regions[4].

Recent investigations of the effects of carbon tetrachloride on the synthesis and secretion of hepatic lipoproteins have outlined in broad detail the mechanisms of this part of the overall disturbance[5]. However, despite such encouraging signs of advance along the one pathway, little progress has been made in unravelling the associated perturbations proceeding to necrosis. It is the purpose of this communication to consider the latter problem and to suggest a hypothesis accounting for the early damaging actions of carbon tetrachloride on the liver, actions which ultimately result in the appearance of necrosis. Obviously, during the later stages of the injury, the interplay of factors affecting the final result is complex in the extreme (for example vascular changes, hormonal influences, cell–cell interactions). These complications are not included here, where only the very early direct actions of carbon tetrachloride on liver parenchyma are considered. Any hypothesis embracing such effects should supply satisfactory answers to certain basic questions, the more important of which are formulated below and later discussed.

Basic questions concerning the necrogenic activity of carbon tetrachloride. (1) Are the toxic properties of carbon tetrachloride on rat liver due to carbon tetrachloride itself, or is a metabolite, or metabolites, of this substance the active agent? (2) Is the action in the rat direct on the liver or do effects at distant sites have significant importance? (3) Why is the liver necrosis central in nature? (4) If the effect of carbon tetrachloride on the liver is a direct action on the parenchymal cells, what is the intracellular locus of the primary disturbance? Is it diffuse, involving several intracellular components concurrently, or sharply localized on one? (5) Why are new-born rats and certain animal species (for example, chickens) much less sensitive to carbon tetrachloride than adult rats? (6) What are the mechanisms involved in the protective action of the wide variety of substances and treatment shown to be active in diminishing the extent of necrosis following carbon tetrachloride administration?

Several difficulties arise in attempting to answer these questions so long as the hypothesis of the mechanism of action of carbon tetrachloride is based on the belief that its action is solely that of a lipophilic solvent. For example, (*a*) the central location of necrosis while the highest concentrations of carbon tetrachloride in blood reaching the liver enter the portal tracts first; (*b*) the much greater damage in the first few hours to the endoplasmic reticulum, whereas other intracellular particles, also bounded by lipid membranes, apparently suffer much less early disturbance; (*c*) the resistance of the new-born rat although carbon tetrachloride has been shown to reach the liver; (*d*) the restriction of severe necrosis to the liver whereas much higher concentrations of carbon tetrachloride accumulate in other tissues; (*e*) the dissociation of the necrosis and of the accumulation of fat brought about by various experimental procedures. It is suggested in this communication that such difficulties can be overcome by a mechanism based on the concept that, before carbon tetrachloride can manifest its latent necrogenic properties, it has to undergo an activation step.

* Within certain limits the degree of necrosis produced by carbon tetrachloride is proportional to the amount administered either orally or by ventilation. In our colony increasing the oral dose above 0·125 ml. carbon tetrachloride/100 g body-weight has little effect on the final extent of central necrosis, and we shall refer to this level as the standard dose.

Metabolism of carbon tetrachloride. Several reports[6,7] in the past few years have indicated that, after being fed to rats, carbon tetrachloride is metabolized to a limited extent. Following administration of ^{14}C-carbon tetrachloride, ^{14}C-label can be detected in expired air as carbon-14 dioxide and as ^{14}C-chloroform. There is evidence that carbon tetrachloride (or its metabolites) is quickly bound to material in the liver. Following administration of ^{14}C-carbon tetrachloride to rats, material containing ^{14}C-label becomes tightly bound to liver protein. The amount was equivalent to 1 μmole carbon tetrachloride/g wet-weight liver protein[8]. Since only a small proportion (about 2 per cent) of administered carbon tetrachloride enters the liver, this suggests that virtually all this becomes combined with liver material and is not present simply as a dissolved solute in fatty material.

However, none of these data provides any information as to whether the metabolism of carbon tetrachloride is important for its role as a liver toxin, or whether it is a side reaction of little relevance to the problem under consideration. This is obviously a key question, to be answered before one can hope to clarify the reactions involved in the necrogenic activity of carbon tetrachloride.

One way of investigating this question in an indirect manner is to consider the relative necrogenic activities of the series of halogenated methanes in relation to their known ease of chemical decomposition which, in such a closely related series, and in a particular animal species, may be expected to be related to the likelihood of their metabolism *in vivo*.

The carbon–fluorine bond in aliphatic hydrocarbons has a higher bond dissociation energy than a carbon–chlorine bond present in a similar structure[9]. In carbon tetrachloride the bond dissociation energy for a C–Cl bond is 68 ± 3 kcal/mole whereas in carbon tetrafluoride the C–F bond dissociation energy is 121 ± 4 kcal/mole. In $CClF_3$ the C–Cl bond dissociation energy is 83 ± 3 kcal/mole, a substantial increase compared with carbon tetrachloride itself. No values are apparently available for trichlorofluormethane but it can be expected that, even here, the C–Cl bond is less easily broken than in carbon tetrachloride. As a consequence it can be expected that trichlorofluormethane should be rather less easily decomposed (metabolized) *in vivo* than carbon tetrachloride.

Trichlorofluormethane is not appreciably toxic to rats. A large dose was found to give no decrease in liver $NADPH_2$ and no increase in the activity of certain serum enzymes[10]: changes characteristic of carbon tetrachloride intoxication. Rats maintained in an atmosphere of 50,000 p.p.m. trichlorofluormethane for 30 min did not develop liver necrosis[11].

What significance do these observations have in relation to the mechanism of action of carbon tetrachloride? One obvious interpretation is that at least some of the administered carbon tetrachloride has to undergo a chemical transformation before its necrogenic potentialities are fully revealed. The increased stability† of the trichlorofluormethane molecule appears to prohibit this possibility to any significant extent. Further indications that carbon tetrachloride alone is inadequate for the development of necrosis are mentioned later. Of course, the necessity for an activation step does not mean that the ensuing damage is not modified nor even greatly extended by the presence of the non-metabolized carbon tetrachloride itself.

The idea that some form of transformation is necessary to explain the hepatotoxicity of carbon tetrachloride has occurred independently to several other investigators, but the full implications of such a reaction to the problems associated with the necrogenic action of carbon tetrachloride on the liver do not appear to have been discussed. Butler[7] suggested that conversion to an ionized form, possibly a free radical, was important. Glynn[12], Fassett[13] and Reynolds[53] have suggested the probability that some form of metabolism is necessary. At present, however, no direct evidence is available concerning the mechanism by which carbon tetrachloride is activated; it need not, however, be a heterolytic process as suggested for certain lachrymatory halogeno-compounds[14]. In fact, if 'activation' occurs in a lipid-rich membrane, in conjunction with an endogenous free radical-producing process, a homolytic, non-ionic, bond scission to produce a free-radical product would appear the more favoured.

In connexion with the suggested activation stage it is important to note that high concentrations of carbon tetrachloride can be detected shortly after administration in such tissues as bone marrow, brain and adipose tissue; significant amounts are found in liver, kidney and muscle[8]. In the rat, however, extensive necrosis occurs only in the liver. If the toxic properties of carbon tetrachloride were due solely to its lipophilic nature and, as a consequence, to unspecific damage to lipid-rich structures, it is strange that those tissues which accumulate it most readily do not suffer the most severe damage. Clearly the indications are that some more specific interaction is necessary for necrosis to develop. The simplest explanation is that carbon tetrachloride is converted to an active form only in those tissues which afterwards become extensively necrotic.

Direct action on the liver. The question arises: are the effects on the liver due to a primary effect of carbon tetrachloride on that organ, or is the carbon tetrachloride provoking a response in some other tissue which then induces the liver changes observed?

The development of satisfactory isolated-liver perfusion techniques[15] has enabled direct tests to be made concerning the effects of carbon tetrachloride and chloroform on the liver (the relationship in chemical structure and properties, and the close similarity of the fully developed hepatic lesions, strongly suggest that carbon tetrachloride and chloroform must act by way of very similar, if not identical, primary mechanisms). Although experiments have not been sufficiently prolonged after infusing carbon tetrachloride or chloroform to demonstrate central necrosis, there is adequate evidence that in such preparations similar changes to those occurring in the intact living animal are occurring in the isolated liver. Decreased cytoplasmic basophilia, disorganization of the endoplasmic reticulum, disturbances in lipoprotein secretion and in protein synthesis have all been demonstrated[16]. It would appear justified, therefore, to conclude that many of the effects of carbon tetrachloride on the liver reflect a primary action of the poison on this organ. It is likely, however, that such changes are themselves modified later by disturbances set into motion elsewhere.

Centrilobular distribution of necrosis. The central location of necrosis has been ascribed to the rapid development of a central ischaemic anoxia[17]. However, although this attractive hypothesis is probably of considerable relevance in later stages of the injury, direct measurements of hepatic blood flow in the first few hours after poisoning have failed to detect significant changes[18]. Further, in an elegant experiment, Brauer *et al.*[19] showed that reversing the course of blood flow through an isolated rat liver preparation (for example, afferent by way of the central vein; efferent through the portal vein) did not affect the central location of early damage caused by chloroform. This last-mentioned finding is of considerable importance, and, moreover, indicates that the 'protective' action of hyperoxic conditions[20] (and the aggravating effect of hypoxia) on the necrosis induced by chloroform and by carbon tetrachloride may be related more to the electronic structure of oxygen (for example its biradical structure) than to its partial pressure in the afferent blood. In a recent

† Until quantitative data on bond strengths, etc., and results with isolated liver preparations are available for trichlorofluormethane, it is impossible to be sure that the increased stability alone is sufficient to account for the relative non-toxicity. Other factors may be of importance *in vivo*, such as an increased rate of elimination; a decreased central uptake; and different solubility properties in intracellular lipids.

discussion of the role of vascular changes in the primary phase of liver injury caused by carbon tetrachloride, Brauer[21] wrote: "Taken together, the circulatory observations, the biochemical data, and the isolated organ experiments indicate clearly that the primary liver lesion resulting from exposure to chloroform or to carbon tetrachloride is independent of any vascular changes, and indeed precedes these in time by several hours, if indeed haemodynamic changes are at all a regular accompaniment of this type of liver injury".

Several other factors may contribute to the central location of the developing necrosis. First, carbon tetrachloride may be preferentially removed from the blood primarily at the centre of the lobules, as are several dyes. In an important investigation, using autoradiography following dosing with ^{14}C-carbon tetrachloride, Rogué and Fèdorko[22] have shown that preferential central accumulation of carbon tetrachloride does in fact occur.

It has already been suggested that an important part of the reactions leading to necrosis is an 'activation' or transformation of carbon tetrachloride. If this reaction were also concentrated in the centrilobular region the effect in terms of cell damage would be synergistic with a preferential central uptake of the poison.

There are numerous examples in the literature of a lobular heterogeneity of enzyme activity obtained by both histochemical and micro-dissection techniques[23]. As a particular example, flavin-linked reactions appear to be concentrated in the central region of the liver lobule. Flavin-coenzymes are known[24] to undergo free radical stages during enzyme-catalysed dehydrogenation and could conceivably act as nidus points for the homolytic cleavage of the C–Cl bond.

Intracellular localization of initial damage. Investigations using ^{14}C-carbon tetrachloride have shown that the ^{14}C-label quickly reaches a high concentration (expressed as mg carbon tetrachloride/mg protein) in the mitochondria and in the endoplasmic reticulum[25]. Thus there is evidence of early accumulation of the poison in lipoprotein-rich membrane systems.

Electron microscopical examination of liver sections from poisoned rats revealed early swelling, disorganization and degranulation of the endoplasmic reticulum but no equivalent damage to the mitochondria, particularly in the central zone, has been observed[26,27]. Biochemical studies have likewise shown that early alterations in the microsome fraction take place. Appreciable changes in the ribosomal population occur 30–60 min after oral dosing with carbon tetrachloride[27]. During this period there is a large decrease in microsomal glucose-6-phosphatase activity[28] and in drug detoxication enzyme systems[29]. Early changes in microsomal NAD(P)-neotetrazolium reductases and in inorganic pyrophosphatase activity have also been found[30].

No similar early biochemical changes have been reported to occur in mitochondrial components (excepting a transient calcium influx)[26] despite the presence of appreciable concentrations of carbon tetrachloride in these organelles. Mitochondria retain citrate[31] and nucleotides[30] until relatively late in the injury, and liver temperature shows no early rise as would be expected from a generalized uncoupling of oxidative phosphorylation[18]. It is worth noting at this point that the early mitochondrial damage reported in histological studies is mid-zonal[32] and not in the central region where necrosis ultimately develops. It is also important to remember, when evaluating results obtained on homogenates, that the data represent a summation of the values pertaining throughout the lobule. What may be a large change in a few cells around the central vein may be hidden by there being no change (or even the opposite tendency) in the remainder of the cells in that lobule.

Apparently the earliest changes‡ produced by carbon tetrachloride in liver cells occur in the microsomal fraction. If activation of carbon tetrachloride is required for the overall injury, then it would appear likely that this process occurs in the endoplasmic reticulum. If the activation stage were a homolytic fission of a C–Cl bond, then systems in the membrane phase involving the controlled production and utilization of free radicals could act as initiators of a new, uncontrolled and powerfully deleterious free radical chain. There are several such natural processes which are believed to occur by way of a free radical stage in the microsomes and which could so act. (For example, the NAD-ascorbate oxidase system[33]; enzyme reactions involving flavins[24]; and the $NADPH_2$–ADP–iron catalysed lipid peroxidation sequence supposedly closely related to the detoxication enzyme systems of the endoplasmic reticulum[34].) It is suggestive that inhibitors of this latter reaction also reduce the extent of central necrosis and/or other toxic manifestations following the administration of carbon tetrachloride: for example, dimethyl-*p*-phenylene diamine[35]; *SKF 525A*[30]; vitamin E[35]. Further, the $NADPH_2$–lipid peroxidation system is only weakly active in liver from new-born rats[30] which are markedly resistant to liver damage induced by carbon tetrachloride[41].

In an interesting report, Tappel and colleagues[36] have shown that intracellular particles bounded by a double lipid membrane (mitochondria) are far less susceptible to disorganization induced by free radicals than are systems bounded by a single lipid membrane (lysosomes). In fact, for equal areas of membrane, approximately 500 times more radicals were required in the first instance than in the latter. It has already been mentioned that carbon tetrachloride is quickly concentrated both in the mitochondria and in the endoplasmic reticulum but that mitochondrial damage is apparently far less severe in the early stages. It is difficult to understand this difference in the degree of damage if carbon tetrachloride is the active agent. However, activation to a free radical form with a subsequent damage can be seen from the results of Tappel *et al.* primarily to favour damage to the endoplasmic reticulum which is limited by a single membrane structure. No oxidative enzyme systems involving free-radical intermediates have been detected in lysosomes, and as a consequence activation of carbon tetrachloride presumably does not occur in these particles. This could provide an explanation of two findings; first, that little damage to the lysosomes occurs during the early phase of carbon tetrachloride intoxication[37]; and secondly, that low concentrations of carbon tetrachloride added *in vitro* to purified lysosomal preparations do not induce rupture, unlike the case with homogenates, where activation can occur in neighbouring mitochondria and microsomal particles[38]. An activation mechanism can thus offer an explanation as to why different types of intracellular lipid-bounded particles are damaged in differing degrees.

It is of interest in view of the proposed free-radical mechanism to note that $NADPH_2$ is very unstable in solution when exposed to a radical-producing system[39]. This might have some relevance to the rapid drop in $NADPH_2$ which occurs after carbon tetrachloride dosing[40].

Resistance of new-born rats. Carbon tetrachloride apparently produces little or no signs of classical necrosis if fed to rats less than about 6 days old[41]. This suggests that new-born rat liver is deficient in some property vital for the toxicity of carbon tetrachloride, and points yet again to the conclusion that the mere physical presence of carbon tetrachloride is not enough to provoke necrosis. On the basis of previous discussion, the lack of toxicity could be due to a lack of activating enzyme resulting in a failure in the formation of the metabolite of carbon tetrachloride which is the active structure responsible

‡ In general, it would be wrong simply to equate earliness of effect with importance of result. Early (possibly reversible) changes may under certain conditions be innocuous compared with some later and irreversible process. With carbon tetrachloride, however, the early damage to the endoplasmic reticulum is very extensive, and many of the changes are prevented by the administration of 'Phenergan', so that it is reasonable to believe that the processes culminating in necrosis have their origin in these early changes in the endoplasmic reticulum.

for the onset of necrosis. There are considerable precedents for such a suggestion. Many enzymes are missing or at most are present to a very limited extent during the first few days of life; in many cases enzyme activity increases rapidly some 2–10 days after birth. It seems plausible that the onset of the necrogenic property of carbon tetrachloride is connected with the rapid appearance of an enzyme activity provoking its activation.

Protectors. It has long been known that various substances which, by themselves, are relatively innocuous, when given together with carbon tetrachloride, either profoundly increase the severity of the ensuing lesion or will so modify the course of the intoxication that liver cell necrosis is greatly diminished[42].

A representative list of protective agents§ is included in Table 1; it can be seen that the substances fall into several groups. In group (*A*) Rees and colleagues[44] have shown that there is a close relationship between protection against necrosis and the physico-chemical properties of the substances concerned. Only those substances which are amphipathic cations at neutral *p*H were effective in reducing the extent of necrosis. Such a relationship does not, however, hold for substances in other groups of Table 1; for example, selenium dioxide, colloidal carbon and molecular oxygen. Clearly the inference must be that if all these substances with such widely disparate chemical structures really do inhibit the development of necrosis other than by secondary mechanisms such as a lowering in body temperature[43], then they are not acting on one locus of disturbance: several mechanisms of protection must in fact be operative.

Table 1. Treatments and Substances Reported to Protect Against Liver Necrosis or other Toxic Manifestations Induced by the Administration of Carbon Tetrachloride

Treatment	Refs.
A. Amphipathic cations	
for example, phenothiazines	44
cetab	
nupercaine	
B. Non-specific inflammation?	
for example, sub-cutaneous injections of carbon, xanthine, etc.	55
C. Lowering in body temperature	
for example, cordotomy	43
adrenalectomy	
D. Antioxidants, chain terminators	
for example, vitamin E	
dimethyl-*p*-phenylene diamine	35
selenium dioxide	
oxygen?	20
cysteamine	30
E. Inhibition of microsomal activation step?	
for example, phenothiazines, *SKF*-525*A*	30,34,44

Such a conclusion is only to be expected if the previous discussion were correctly based. For instance, if the location of necrosis is dependent on the co-operative action of central uptake and central activation, inhibition of either process will afford some measure of protection. Further, since each process is probably the sum of several events, it is presumably possible to interfere with each in more than one manner. This can best be illustrated in relation to the proposed mechanisms for carbon tetrachloride activation.

Fig. 1 gives a scheme which follows the views already propounded. Carbon tetrachloride is 'activated' to a free radical form (assumed to be $CCl_3\cdot$ for the sake of argument) by interaction with a normally occurring homolytic process under metabolic control. The free radicals so formed then interact with neighbouring lipid-rich material causing disturbance in structure and function. Protection against the overall process could be obtained by blocking the endogenous radical system; by removal of the $CCl_3\cdot$ radicals preferentially by combination with excess added acceptor (for example, the protective action of antioxidants); by providing a competitor for carbon tetrachloride in its reaction with the endogenous radical chain yielding a less-toxic product; by promoting the removal of $Y\cdot$ through an increase in the rate of the endogenous reaction (oxygen effect ?); or by unspecific action as in the case of cordotomy where a general decrease in body temperature slows down metabolism overall[43]. The properties required of substances in these five types of interaction could clearly be different.

It can be seen that the acceptance of an activation stage as a necessary event in the development of liver necrosis following the administration of carbon tetrachloride enables a scheme of the above type to be formulated in which a plurality of mechanisms can be envisaged for protective agents. So long as carbon tetrachloride was believed to exert its effects by way of an unspecific lipophilic action, it was difficult to visualize how such a wide range of protective agents could all be effective. Activation provides a key to understanding such a complex sequence of events.

One characteristic of chain reactions is that following initiation there is a lag phase which is greatly prolonged by the addition of chain terminators; ultimately there is a very rapid increase in reaction rate. This behaviour has similarities with the histological development of liver necrosis induced by carbon tetrachloride, which, in its later stages (12–18 h), develops with an explosive violence. This necrogenic reaction can be temporarily inhibited by a suitable dose of a phenothiazine drug such as 'Phenergan'[45]. The phenothiazines are known to be capable of forming free radicals[46] and possess the —S—C = C—N— grouping which has powerful quenching properties[47]. 'Phenergan' inhibits flavin-linked enzymes[48], probably by way of a free-radical stage, and inhibits very strongly the $NADPH_2$–lipid peroxidation process present in liver microsomes (50 per cent inhibition at 30 μM final concentration, *in vitro*[30]). Although part of the long-term protective influence of phenothiazines on rats treated with carbon tetrachloride is no doubt due to an effect in lowering body temperature[49], there appears ample evidence that more direct protective actions are operative in the early stages. The most likely is an interference with free radical producing systems in a lipid interface.

The preceding discussion has led to the suggestion that an important aspect in the necrogenic activity of carbon tetrachloride on rat liver is a so-called activation stage in which either carbon tetrachloride itself is metabolized to a powerful destructive free radical form or, by its presence, induces the formation of other and equally deleterious radicals. The intracellular production of significant quantities of extraneous free radicals (that is, radicals not associated with a controlled metabolic sequence) can be expected to produce severe damage near the site of formation. In the presence of lipid-rich mem-

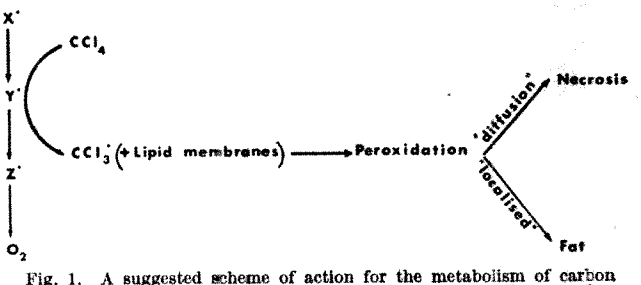

Fig. 1. A suggested scheme of action for the metabolism of carbon tetrachloride *in vivo* via an interaction with a naturally occurring homolytic chain reaction ($X\cdot$, $Y\cdot$, $Z\cdot$) in the endoplasmic reticulum. As a result of such an interaction, extraneous radicals are produced (shown here as CCl_3) which, in the presence of lipid-rich materials and oxygen, result in peroxidative damage to intracellular membranes. At some point in this reaction the processes leading to necrosis and to the accumulation of fat probably diverge. The possibility that one mechanism for such a divergence of effects can be based on the extent of diffusion of the free radicals produced by the metabolism of carbon tetrachloride is speculative. Furthermore, it is not intended to suggest (see text) that an activation process, such as depicted in Fig. 1, is sufficient to produce the full consequences of carbon tetrachloride intoxication, but only that an activation step is a necessary feature of the injury

§ The criteria used in assessing protection have varied widely[42]. In some cases it has been effectiveness in reducing death rate; in others, the effectiveness in preventing rises in serum enzyme-levels; in others, the effect on the histologically assessed parameters of fat and necrosis. Since the demonstration[43] that a decreased body temperature can effectively inhibit liver damage caused by carbon tetrachloride, it is evident that many early reports claiming protection for a variety of materials will have to be checked for possible variations in body temperature.

branes and of oxygen, lipid peroxides could be formed with a consequent loss of structural function and organization. Damage to mitochondria[50], lysosomes[51] and the endoplasmic reticulum[34] has been reported following the experimental initiation of lipid peroxidation. This type of consequence appears the most likely following the initiation of extraneous free radical production in the cytoplasm. It has already been mentioned that the probable sites of extraneous free radical formation following carbon tetrachloride administration are the mitochondria and the endoplasmic reticulum. The results of Tappel *et al.*[36] indicate that a structure bounded by a single lipoprotein membrane (for example, the endoplasmic reticulum) would be far more sensitive to damage induced by free radical attack than a double-layered membrane as in the mitochondria. A further and probably important factor favouring preferential early damage to the endoplasmic reticulum is the concentration of endogenous antioxidant material (for example, tocopherol and ubiquinone) in the mitochondria[52]. This can be expected to stabilize these particles against the type of mechanism suggested here. Finally, it is worth mentioning that, in agreement with speculations made here, and since this manuscript was prepared, Recknagel and Ghoshal[54] have reported an increased lipid peroxidation in liver microsomal fractions isolated from rats poisoned with carbon tetrachloride.

I thank Prof. C. Rimington and Dr. K. R. Rees for stimulating and encouraging my interest in this problem, and Dr. C. R. Patrick for advice on the section concerning the metabolism of carbon tetrachloride and on the stability of trichlorofluormethane. Sir Roy Cameron very kindly read the manuscript and made most helpful comments derived from his very extensive knowledge of the subject.

AGGREGATION OF TUMOUR CELLS

By Prof. EDWARD O. DODSON*

Tissue Culture Laboratory, Roswell Park Memorial Institute (New York State Department of Health), Buffalo, New York

Moskowitz[1,2] and Moskowitz and Amborski[3] have investigated the formation of aggregates by various mammalian tumour cells in tissue culture. They found that agitation by shaker or roller drum induced aggregation in the cell lines investigated, as did the use of a protein-free medium or the addition of equine β- and γ-globulin fractions to stationary cultures. These aggregates grew to as much as 5 mm in diameter, when the surface became grooved and the aggregates divided. Because these aggregates have a differentiated surface membrane and an inner cell mass of less oriented cells, Moskowitz[2] suggested that they be called 'aggregens', which he states "fulfil all the criteria which are applied to the description of an independently living organism. From another point of view, they can be regarded as free-living tumours". Moskowitz distinguishes between

* Present address: Department of Biology, University of Ottawa, Ottawa 2, Ontario, Canada.

'clumps', which are accidentally formed groups of cells, and 'aggregates' or 'aggregens', which represent at least a partial expression of the developmental potential of the cells. The purpose of this article is to report experiments on aggregation of several more lines of tumour cells.

Six cell lines from the RPMI collection were examined: RPMI Nos. 2650, 2650-*LN*-2, 2650-*R*, *T*-3-1, 6410, and *WI*-38. The first three are all derived from a pleural effusion of a patient with squamous-cell carcinoma. Chromosome investigations[4] show the normal diploid count of 46, although human tumour-cell lines are usually aneuploid, most commonly near-triploid. Reasons for considering the cells of this line to be tumour cells, rather than normal cells selected from a mixed population by the culturing technique, were summarized by Moore and Sandberg[4]. Briefly, they include the following: successful heterotransplantation to conditioned mice; resemblance of the heterotransplants to the original tumour; injection into volunteer patients and resemblance of the resulting growth to the original tumour; and, finally, successful culturing through many passages. The line is now in its seventy-fourth passage, and it has been maintained in culture for three years.

Hayflick and Moorhead[5], in an exhaustive investigation of human diploid cell strains, found that they could not be maintained for more than a limited (though perhaps large) number of passages, nor for much more than a year. They consider the alteration of a cell strain to form a potentially immortal cell line to involve mutation to aneuploidy. Although RPMI 2650 is diploid, the genotype may have been significantly altered in other ways. In view of the age of this cell line, it seems probable that it could be maintained indefinitely. Collectively, the reasons cited comprise a strong presumptive case for its malignant character.

RPMI 2650 is the unmodified cell line. In stationary cultures, it forms a good monolayer; and in suspension cultures, the cells are well dispersed, with only occasional small clumps. RPMI 2650-*R* was X-irradiated four times, the total dosage being 7,000 r. It grows more slowly than 2650, and is much more difficult to maintain. In stationary cultures, the cells grow in clumps or aggregates of a few cells to several hundred cells (Fig. 1). These have very little tendency to spread over the glass. In suspension cultures, they form aggregates that tend to fall out of suspension. Viability tests show that almost all the dissociated cells are non-viable. The chromosomes again number 46, but one of the smallest chromosomes (21 ?) is deficient and resembles the Philadelphia chromosome.

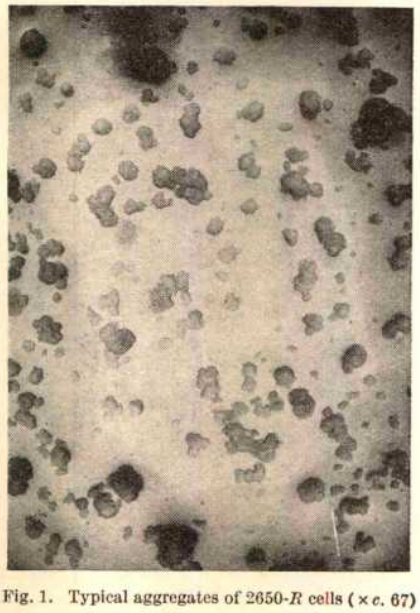

Fig. 1. Typical aggregates of 2650-*R* cells (×*c.* 67)

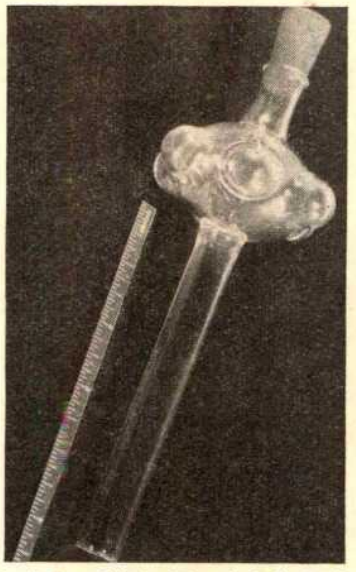

Fig. 2. A Steward flask. The ruler indicates the size

RPMI 2650-*LN*-2 is a spontaneous mutant of 2650, one that suggests 2650-*R* in some of its characteristics. In stationary cultures, it adheres to the glass in a reticular pattern, interrupted by occasional aggregates, which, however, have a more regular appearance than do those of 2650-*R*. In suspension cultures, it forms many aggregates that tend to settle out. RPMI *T*-3-1 and 6410 are both myeloid leukaemia cell lines that tend to form aggregates spontaneously in stationary cultures. Finally, *WI*-38 is a line of normal human embryo fibroblasts.

Media used include the following: RPMI 906 with foetal calf serum varying from 0 to 30 per cent; McCoy's medium 5*A* with either 10 or 20 per cent serum; RPMI 1629 with 30 per cent serum; RPMI 1630 with 5 or 10 per cent serum: or RPMI 1595 with 5 per cent serum. Stationary cultures were grown in *T*-flasks of 30-ml. capacity with 6 ml. of medium, or of 60-ml. capacity with 12 ml. of medium. Some of these were agitated by placing them on a Clay-Adams rotary shaker set for its lowest speed (90 r.p.m.). Others were grown in a new type of vessel consisting of a 50-ml. bulb with six small wells around the circumference (Fig. 2). The bulb is fused to a glass tube, by which it is mounted on a roller drum. As the drum rotates (about 1 r.p.m.), the medium is poured from one well to the next, thus maintaining constant, mild agitation. The volume of medium used was 5 ml., sufficient to fill two wells at a time. Because these vessels are based on similar, though much larger, flasks used in the laboratory of Prof. F. C. Steward for culturing plant cells, we call them 'Steward flasks'.

After aggregates were well established, the strength of cell adhesions was tested by putting them on a Boerner shaker, either in the growth medium, in EDTA, or in trypsin, and trying to disrupt them. Cell counts in the supernatant served as an index of dissociation of the aggregates.

Because of the importance of the part played by mesoderm in the organization of the embryo, mixed cultures of *WI*-38 (fibroblasts) and 2650 (epithelial cells) were made. A similar test was made with another fibroblast line (RPMI 4269) obtained from a tumour.

The effects of various concentrations of protein in the medium on aggregation were determined by growing cultures in medium 906 with foetal calf serum added in concentrations of 0, 5, 10, 20 and 30 per cent. The cell lines examined were 2650, 2650-*R* and *WI*-38. The medium was not changed during the course of the experiment; but cultures were fed by the addition of glucose solution.

WI-38 cells, a fibroblastic line, were badly damaged by culturing on the protein-free medium. After five days, the

cultures were sparse, the cells looked moribund, and there was no tendency toward formation of aggregates. After 10 days, the cells were much shrunken, and the protoplasm appeared scant. Cells tended to draw into cords, which formed a network on the glass. Many sloughed off into the medium, and these were all dead, as indicated by uptake of trypan blue. The five cultures in this series were discarded after 10 days. Controls on McCoy's medium with 10 per cent foetal calf serum grew vigorously throughout the experiment.

In a preliminary experiment to test the effect of protein concentration on cells of line 2650, five cultures of 2650 were set up in medium 906 without serum and five more in 906 with 5 per cent foetal calf serum. Similarly two cultures of 2650-*R* were set up in protein-free 906, and three in 906 with 5 per cent foetal calf serum.

After one week, the 2650-*R* controls were well established and showed the growth pattern typical of the line. They continued good development throughout the experiment. The experimentals, however, showed insufficient growth to establish the typical pattern. After 10 days, they were becoming sparse; and after two weeks, the cultures were dead. The 2650 controls grew rapidly and became heavy during the experiment. Those on the protein-free medium remained light. Some aggregates formed and sloughed off into the medium, but they did not grow. They were discarded after 18 days of 'growth'.

In another experiment with 2650, three cultures each were grown in medium 906 with foetal calf serum supplements of 0, 5, 20 and 30 per cent. Those in the protein-free medium followed the course already described. Clumps of cells were formed, but no aggregates. After eight days, these were discarded. Meanwhile, the controls in 906 with 5 per cent of foetal calf serum had formed a good monolayer, which was maintained throughout the experiment, although excess cells sloughed and died. Within 5 days, the cultures with 20 per cent foetal calf serum showed many cells in the medium, including clumps, but no aggregates. After a week, there were perhaps more cells in the medium than on the glass, and yet most of these were dissociated cells or clumps, with very few aggregates. Most of the cells in the medium proved to be non-viable when stained with trypan blue. After 10 days, many of the cells remaining on the glass were arranged in small clumps that resembled small aggregates of 2650-*R*. Many of the cells were vacuolated, pale, and more broadly spread out than normal cells. These cultures were maintained for nearly three weeks, but further changes were mainly degenerative.

The cultures in 30 per cent serum were similar to those in 20 per cent, but they left the glass more rapidly and more extensively. The viability of cells in the medium was very low. Cells which remained on the glass were commonly arranged in groups suggestive of the smaller aggregates of 2650-*R*, and hence it may be that a high serum level in the medium does promote aggregation of cells of line 2650.

Efforts were also made to promote aggregation by placing cultures in T-flasks on a rotary shaker. Cultures were put on the shaker at its minimal speed (60 r.p.m. according to the dial, but actually 90 r.p.m.). After one week, there were many cells of 2650 in the supernatant. These formed many clumps, but no aggregates. The cells that remained on the glass were not evenly distributed; they were arranged in clusters suggestive of the aggregates of 2650-*R*, but they never formed clear-cut aggregates.

When cultures of 2650-*R* were similarly treated, aggregates of 64 cells or more came off the glass within two days. Within four days, almost all cells were in the medium, and some aggregates were as much as 5 mm in diameter. Some were sheet-like, others more string-like in form. Within six days, most of the cells had died.

In heavy cultures of *WI*-38 cells, macroscopic fibrous structures, looking like fragments of white thread up to 2 mm long, appeared. Microscopic examination showed these to be tightly aggregated cells, all oriented lengthwise with the thread, and suggesting early stages in the formation of connective tissue. Between these heavy, macroscopic concentrations were lighter ones, often in the form of a network. Such cultures were placed on the rotary shaker. Within two days, all the cells appeared to be concentrated in a single mass about 3 mm in diameter and less than 1 mm thick. The trypan blue test showed that most of the cells were viable. Two days later, however, this cell mass stained intensely, showing that most of the cells had died.

The first experiments with Steward flasks were run with a very slowly revolving drum, which made one complete revolution in five minutes. Later experiments were run at 1 r.p.m., but the results were similar. RPMI 2650 cells soon settled on the glass, especially in the wells. There they became arranged in streaks running in the direction of the flow of the fluid. These streaks tended to become confluent, but there was no tendency to form aggregates. When inoculated into siliconized Steward flasks, however, the cells did sometimes form aggregates; and, contrary to expectation, these quickly settled out on the siliconized glass. These aggregates were 0·5–1·0 mm wide, and they were elongated in the direction of flow. In some areas, they formed extensive networks. After eight days, counts of cells in the supernatant were made. The average was 9 viable cells per mm^3. Most of these were dissociated, but twos and threes were seen.

After shaking in the medium for 10 min on the Boerner shaker, no increase in turbidity was noticed. The cell count had risen only to 12 per mm^3, and all cell masses were still on the glass. The medium was then replaced with EDTA, and the flask was returned to the shaker. Fragments began to break off almost immediately. After shaking for 10 min, the count in the supernatant was 62 per mm^3. After 20 min, all the masses were off the glass, and the count in the supernatant averaged 594 per mm^3. Only 10 per cent of the cells were fully dissociated, however, the rest still being in aggregates, many of them too large to permit counting. After 30 min, the viable cell count had risen to 1,500 per mm^3. Results with trypsin were similar, but dissociation was slower in early stages.

RPMI 2650-*LN*-2 cells tended to remain in suspension in the Steward flasks. They formed numerous small aggregates less than 1 mm in diameter, and an occasional larger one, with a diameter up to a maximum of 4 mm. These cells were easily dissociated, for after shaking for 10 min in EDTA, no true aggregates were left, although there were still some clumps. For example, a culture which was set up with an inoculum of 300,000 cells was gathered after one week. Before shaking in EDTA, a count showed 50 viable cells per mm^3, in the supernatant, when it had an abundance of small aggregates. After 10 min of shaking, there were 726 cells per mm^3, or 3,630,000 in the culture. Results were more variable with 2650-*LN*-2, however, than with 2650 or 2650-*R*.

RPMI 2650-*R* cells aggregated very rapidly in the Steward flasks. Overnight, numerous small aggregates, 1 mm or less in diameter, settled on the glass of the wells. A few larger aggregates were formed as quickly. For example, one was observed which was about 4 mm long by 2·5 mm wide (Fig. 3). Such aggregates were generally elongated in the direction of flow. Within a week these would grow and anastomose to form an extensive network over the surface of the wells. A single strand might extend as much as 2 cm, and the breadth of strands varied from 0·5 mm to 5–6 mm.

Typically, all the viable cells were confined to the aggregates. They were very firmly bound, for shaking in the medium did not break up the aggregates or free them from the glass. When the cultures were shaken in EDTA, pieces began to break off the glass almost immediately, but fairly large aggregates remained on the glass after shaking for 10 min. After 20 min, the largest mass was reduced to

about half its initial size, and the supernatant contained many small aggregates. After 30 min, there were many small aggregates in the supernatant, and the largest were about 2 mm in diameter. Even after 40 min, there were still many small aggregates and clumps, although there were also many dissociated cells. In another run, they broke down more quickly. After 10 min of shaking in EDTA, a count of 1,352 viable cells per mm³ was obtained, although many of these were in small aggregates and clumps. After 20 min, all cells were either dissociated or in small clumps, most commonly of two or three cells. There were not aggregates. On shaking in trypsin, similar results were obtained, but the early stages of the break-up of the aggregates went more slowly.

T-3-1 cells were also examined in Steward flasks. These cells formed abundant small aggregates, 1 mm or less in diameter, within a few days. Within a week, a very few larger aggregates, up to 5 mm in diameter, were formed. These larger aggregates tended to become perforated and rather lacy in appearance, and then they broke up into many small ones. Most of these remained in the medium, but a few adhered lightly to the glass. After two weeks, the cultures appeared to be dying, and they were discarded.

Experiments with RPMI 6410 and *WI*-38 in Steward flasks were less productive. RPMI 6410 cells grew very satisfactorily in the Steward flasks, but they occurred almost entirely as dissociated cells. A few small clumps of 2–4 cells were seen, but no aggregates. It is interesting to note that these cells are derived from myeloid blood cells, which, as dissociated cells, form an important part of the circulating blood *in vivo*. When grown in stationary cultures, they form large aggregates spontaneously; but in mildly agitated Steward flasks, they are again almost completely dissociated. *WI*-38 cells failed to grow at all in the Steward flasks, and the cultures soon died.

Because of the importance of mesodermal tissues in embryonic induction, mixed cultures of epithelial and fibroblast cells were set up. The principal combinations used were *WI*-38 (fibroblasts) added to established cultures of 2650 and 2650-*R*, 2650 added to established *WI*-38, 2650-*R* added to established *WI*-38, and *WI*-38 and 2650-*R* inoculated simultaneously. In addition, 2650 and 2650-*R* were added to another line of fibroblasts, RPMI 4269, which was derived from an epithelial tumour. The fibroblasts, however, had taken over the cultures from this tumour.

The most productive experiment was the addition of 2650-*R* cells to established cultures of *WI*-38. Within a few days, it appeared likely that the 2650-*R* aggregates were elongating along the *WI*-38 cells as guides. After a week, this was clearly the case. After two weeks' growth, the 2650-*R* aggregates had assumed bizarre shapes never suggested in the pure cultures, and those shapes always corresponded to the distribution of the *WI*-38 cells. The typical 2650-*R* aggregate is a compact round-to-oval cluster, looking superficially much like a grain of sand (Fig. 1). In the mixed cultures, they were elongated, often branched, and sometimes took on turtle-like and other highly modified configurations, conforming to the distribution of the underlying *WI*-38 cells. After about three weeks, the cultures were very heavy, and the largest aggregates began to disorganize.

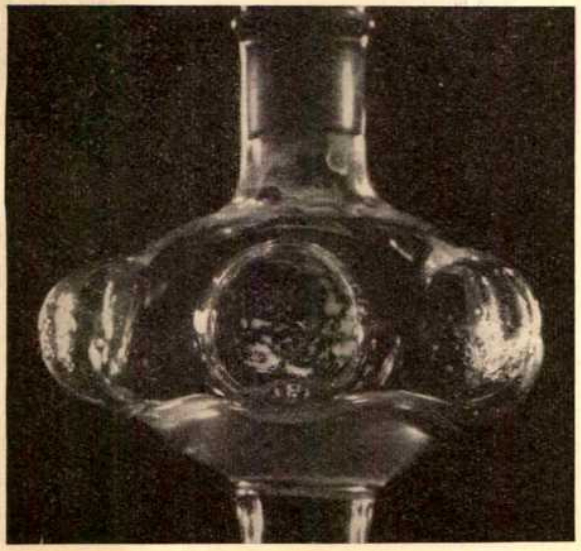

Fig. 3. Recently established aggregates of 2650-*R* cells growing in a Steward flask

The reciprocal experiment, addition of *WI*-38 cells to established cultures of 2650-*R*, was much less productive. After 9 days, a suggestion of elongation of some of the 2650-*R* aggregates along the fibroblasts was seen. Although the cultures were maintained for more than a month, the elongation never developed much beyond a suggestion. Much the same thing was true when 2650-*R* and *WI*-38 were simultaneously inoculated into new cultures. Apparently the capacity of established *WI*-38 cultures to direct the organization of newly forming 2650-*R* aggregates does not extend to other combinations of the two cell types.

RPMI 2650 cells did not appear to be influenced by *WI*-38 cells in any combination. Cultures were maintained for four weeks, but neither cell type ever showed any tendency to interact with the other or to orient its growth in any way different than the pure cultures.

Epithelial cells were also added to established cultures of fibroblasts derived from biopsy of a cancer patient, RPMI 4269. These fibroblasts grow vigorously, in typical fibroblast fashion. To each of a series of well-established cultures in T-30 flasks, 300,000 RPMI 2650 cells were added. Within 3 days, all of the RPMI 2650 cells had disappeared, a fact that may be related to the failure of the epithelial cells in the original culture (and perhaps to the death of the patient). The cultures were then re-inoculated with 400,000 cells each. The following day, the RPMI 2650 cells again seemed to be dying out, except in one culture, in which the fibroblasts had been sparse from the start. After two weeks, however, some epithelial cells were still recognizable, although the fibroblasts were strongly predominant in the cultures. After two and a half weeks, no 2650 cells at all were identifiable in one culture, and they formed no more than a small minority in any of the others.

When 2650-*R* cells were added to 4269 fibroblasts, the results were quite different. Initially, the epithelial cells regressed, and the individual aggregates had a rather constricted appearance. They were confined to spaces between the sheets of fibroblasts, and they seemed to regress. After 10 days, however, some growth was evident. They were still confined to spaces between fibroblasts, where they might grow out in long, narrow tongues, quite unlike their normal pattern or their pattern of growth on *WI*-38 cells. After two weeks, this pattern was prominent; and after two and a half weeks, the aggregates looked heavy enough to suggest the possibility that they might soon overwhelm the restrictive influence of the fibroblasts.

The suggestion made by Moskowitz[2] that cultured aggregates of tumour cells "can be regarded as free-living tumours" is plausible. If it is correct, then the examination of such aggregates should be even more *à propos* to the problem of cancer than the study of the same cells in monolayers.

Both the conditions of culturing and the inherent characteristics of the cell influence the aggregation of cells. No conditions were found under which 2650-*R* did not form aggregates, but these aggregates seldom reached large size. The largest in stationary cultures were about 2 mm in diameter. The centres of these would break out, leaving a ring that fragmented into many smaller aggregates. In Steward flasks, larger aggregates were formed because of the tendency of the aggregates to elongate in

the direction of flow. In extreme cases, these might reach a length of 2 cm and a maximum breadth of 3–4 mm, but their outlines were always highly irregular. The tenacity of the cell adhesions is shown by their resistance to separation on the Boerner shaker. Prolonged shaking in the growth medium did little or no damage. Shaking in EDTA or trypsin did break the cells apart, but some aggregates generally remained after shaking for 20 min, and small clumps remained even after half an hour.

In contrast, it was very difficult to induce aggregation of RPMI 2650 cells. They did show a very limited tendency to aggregate in cultures with high content of foetal calf serum, or in siliconized Steward flasks. Aggregation in the latter was a sporadic event, and its causes have yet to be determined. When aggregated, however, the adhesion was quite tenacious: shaking in the medium had no effect, and shaking in EDTA or trypsin required about 30 min to reduce the aggregates to dissociated cells.

Line 2650-*LN*-2 shares characteristics of its sister lines. In stationary cultures, the cells formed small, very regular, oval aggregates, but it was difficult to increase the size of the aggregates by experimental techniques. Larger aggregates developed sporadically in Steward flasks, and this behaviour remains to be investigated.

Cells of 6410, a myeloid leukaemia line, formed large aggregates spontaneously in stationary cultures. The largest was nearly 4·5 cm long and had the form of a tongue worm, with the ovoid 'body' about 2 cm long and the narrow 'tongue' about 2·5 cm long. The borders of these large aggregates were not sharp, as Moskowitz believes they should be, yet I believe that such clusters are true aggregates in Moskowitz's sense of the term, for several reasons. Their formation under the conditions of culture was invariable. Almost all the cells in the supernatant were dead, whereas almost all those in the aggregates were living. Finally, even the general form was fairly constant—always an irregular ribbon. In view of these facts, it seems clear that these are not accidental assemblages of cells. They are true aggregates, resulting from the developmental potential inherent in the cells. These aggregates, however, are not stable. It is difficult to handle the culture dishes without dispersing the aggregates to some extent: and as gently as the cultures were agitated in Steward flasks, the aggregates were completely broken up in them, and only infrequent clumps of 2–4 cells were seen.

T-3-1 cells form large aggregates (4–5 mm in diameter) spontaneously in stationary cultures, yet these are so weakly bound that the gentle agitation of the Steward flasks breaks them down to a much smaller size. Finally, *WI*-38 cells did form small fibres spontaneously in stationary cultures, and they did form a single large mass when cultures were kept on a rotary shaker; but the cells soon died after forming such a mass.

To summarize in embryological terms, competence to respond to the conditions for aggregate formation varies widely among the cell lines studied, from a maximum in the case of 2650-*R* to a minimum in the case of 2650. *WI*-38 cells have a very low competence for aggregation, but they do display some potency for guiding the aggregation of 2650-*R* cells. That this potency should characterize an embryonic line of fibroblasts rather than the adult line which was also tested is hardly surprising.

I thank Dr. George E. Moore for the facilities of his laboratory and his advice. This work was supported by research grant 1–S01–*FR*–05250–01 of the U.S. Public Health Service, awarded to Dr. G. E. Moore.

A NEW GENETIC VARIANT OF β-THALASSAEMIA

By R. C. SCHOKKER, Dr. L. N. WENT and Dr. J. BOK
From the Departments of Human Genetics and Endocrinology, University of Leiden, and the City Hospital, Dordrecht, The Netherlands

THE heterogeneity of thalassaemia is well recognized; but the marked diversity of its manifestations has complicated the many efforts[1–7] for classification. General agreement exists about a primary sub-division into α- and β-thalassaemias, following the suggestion of Ingram and Stretton[8]. A further sub-division of β-thalassaemias is difficult since genetic or environmental modifiers may be involved.

We wish to present a family with a hitherto undescribed form of β-thalassaemia, in which the unusual findings must be explained on the basis of a single gene defect with very constant phenotypic expression.

In Fig. 1 the pedigree of this family is reproduced. It can be seen that the presence of homozygotes in this family is a result of the fact that the parents are second cousins and both carry the abnormal gene. The family was traced back as far as 1720 and seems to be of pure Dutch stock.

The two homozygotes in this family (*V*-27 and *V*-28), both about forty years old, are unusual in various respects. They have reached adult life without any serious illnesses; only occasional bouts of jaundice were reported to have occurred in *V*-28. A very marked increase of erythropoietic activity—also resulting in considerable radiological abnormalities of the skeleton—leading to a well-compensated anaemia with haemoglobin-levels of 12·1 and 14·3 g/100 ml. is present in the two brothers. The morphology of the red cells is, although not at all classical for thalassaemia major, nevertheless rather abnormal (Fig. 2). The presence of numerous nucleated red cells in the index case dates from 1953, when he underwent a splenectomy.

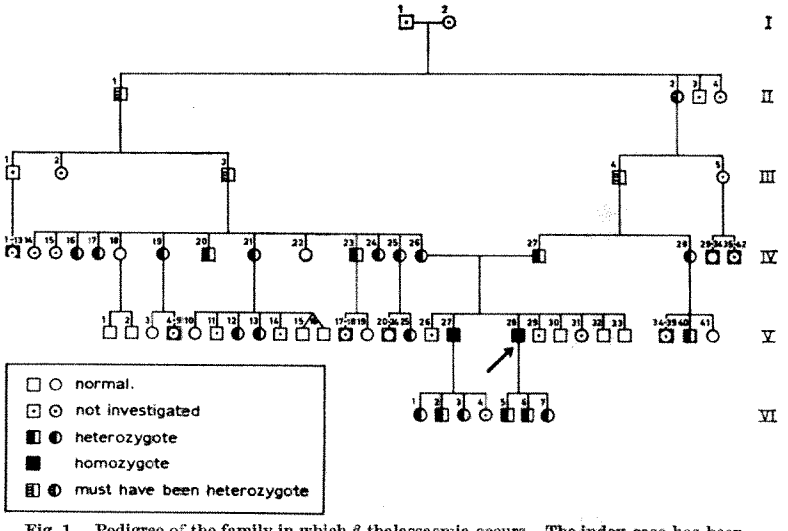

Fig. 1. Pedigree of the family in which β-thalassaemia occurs. The index case has been indicated by an arrow

The haemoglobins of the homozygotes were investigated on various occasions by different electrophoretic techniques and by chromatographic studies on 'Amberlite *IRC* 50' and DEAE–cellulose. Neither with these techniques nor with an immunological analysis using anti-Hb A serum could any Hb A be detected. The only haemoglobin components present were Hb F, which varied in concentration between 98 and 98·8 per cent, and Hb A_2 which formed the remainder. Analysis of these Hb F and Hb A_2 fractions by fingerprinting gave findings indistinguishable from those of normal Hb F (cord blood) and normal Hb A_2.

The three non-investigated siblings of the two homozygotes died before the age of one year from causes probably unrelated to the genetic defect of their brothers. The six investigated children from the homozygotes could only be partially examined since no permission was given for venepuncture. Nevertheless the findings from finger-prick blood (red cell morphology, mean corpuscular volume (MCV) and Hb F-levels) leave no doubt that they are all actually heterozygotes for the thalassaemia gene in question.

Both parents and 13 other relatives of the two brothers in generations IV and V appear to be heterozygotes for a β-thalassaemia and present a haematological picture which is in all respects typical for thalassaemia minor. A further 24 relatives were, on haematological examination, entirely normal. The red cell morphology of the heterozygotes conformed to the usual one for β-thalassaemic heterozygotes, including marked basophil stippling, while the MCV had an average value of 73 μ^3 and the mean corpuscular haemoglobin concentration (MCHC) an average value of 31 per cent. The haemoglobin A_2 level (determined by starch-block electrophoresis at *p*H 8·6) was raised in all heterozygote individuals, together with a marked increase in foetal haemoglobin (as determined by the alkali denaturation technique).

The Hb A_2 concentrations varied between 5·3 and 7·6 per cent (with an average of 6·6 per cent) of total haemoglobin whereas the Hb F content varied between 5·1 and 14·4 per cent (average 8·3 per cent). These results

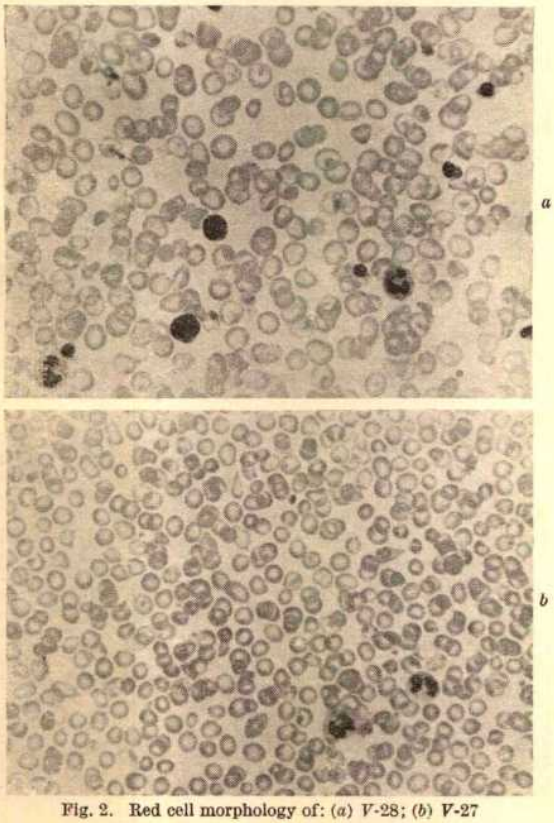

Fig. 2. Red cell morphology of: (*a*) *V*-28; (*b*) *V*-27

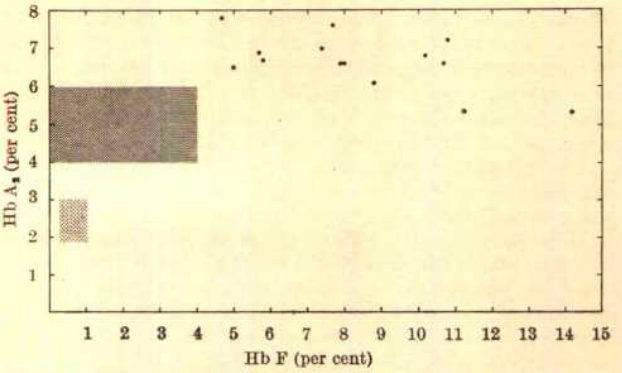

Fig. 3. Hb A_2- versus Hb F-levels in 14 heterozygotes and 24 normal individuals from the family of Fig. 1, compared with the range of usual findings in β-thalassaemia heterozygotes (shaded area). The findings on the 24 normals come too close together to be individually indicated and are therefore represented by the stippled area

were confirmed by parallel investigations in different laboratories both in Holland (Amsterdam and Leiden) and in the United States (Atlanta, Georgia). They are definitely very unusual when compared with the common findings in β-thalassaemia: Hb A_2 ranging between 3·5 and 7 per cent (with an average of 5 per cent) and Hb F ranging between 0·3 and 6·5 per cent[2,9–12]. The distribution of Hb F over the red cells of the heterozygotes, using the acid elution technique of Kleihauer-Betke[13], was found to be very uneven. Moreover, the 24 non-thalassaemic family members had Hb A_2-levels between 1·9 and 3·0 per cent, and Hb F-levels below 1 per cent (Fig. 3), therefore completely in agreement with findings from the literature on normals.

The genetic defect in the family described is in our view undoubtedly a form of β-thalassaemia. The heterozygotes conform in all respects to the accepted criteria for β-thalassaemia, that is, an increased level of Hb A_2, a typical morphological picture with a low MCV in the presence of a normal MCHC and an uneven distribution of Hb F over the red cells[12]. The two brothers (*V*-27 and *V*-28) are undoubtedly true homozygotes since their parents are second cousins and the mutation in question must be extremely rare. A severe impairment of β-chain synthesis (evidence for β-thalassaemia) exists since no Hb A is formed at all.

The difference with the usual heterozygous form of β-thalassaemia is evident since in our family the average Hb A_2-level is higher (6·6 per cent against 5 per cent) and the average Hb F-level (8·8 per cent) is above the highest reported figures which range for the usual form from normal to 6·5 per cent. In Fig. 3 the Hb F- versus Hb A_2-levels for 14 of the 15 adult heterozygotes are individually plotted. For comparison are also indicated the area in which all the findings on the 24 normal individuals of our family belong and the area in which approximately 95 per cent of reported findings on the common β-thalassaemia heterozygotes fall.

The absence of Hb A in our homozygotes appears to be rather unusual when compared with the more common thalassaemia homozygotes, but has recently been described with considerable frequency notably by Fessas from Greece[7,14,15]. In a personal communication, Weatherall (1964) has reported the finding of two sisters with fairly mild thalassaemia major with complete absence of Hb A. In the heterozygous state of these thalassaemias from Greece and the United States, however, the more usual form of β-thalassaemia with only a minor increase of Hb F appeared to be present.

Recently, many instances of apparently true β-thalassaemias with markedly increased levels of Hb F—which is unevenly distributed over the red cell population—have been reported[3,7,14,16]; in this so-called F-thalassaemia or β-chain thalassaemia type II (Fessas), however, the A_2-levels are without exception within the normal range. Homozygotes for this condition appear not to have been

described up to now. (*Note added in proof.* C. Brancati reported at the "Dixième congrès de la Société Européene d'Hématologie" in Strasbourg, August 1965 (résumé No. 270), a near-certain case of homozygosity of this F-thalassaemia. The haemoglobin consisted of Hb F only, with complete absence of both Hb A and Hb A_2.)

The hereditary persistence of foetal haemoglobin or the high F gene[2,12,15] is undoubtedly a genetically different entity because in the heterozygote carriers of this F gene a normal red cell morphology, a slightly decreased Hb A_2-level and an even distribution of Hb F over the red cells are being found[12]. The only reported case of homozygosity for the high F gene[17] is not anaemic. This 2-year-old girl also completely lacks Hb A, but in contradistinction has no Hb A_2 either.

On the basis of all these arguments the family described must carry a new type of β-thalassaemia mutation and provides further evidence for the genetic heterogeneity of thalassaemia. A further comparison and analysis are presented elsewhere[18].

The first discovery of the thalassaemic nature of the abnormalities in our family was made by Drs. H. K. Prins and M. Oort from the Central Laboratory of the Netherlands Red Cross Blood-transfusion Service in Amsterdam. We thank Dr. F. Westendorp Boerma for the immunological investigations, Dr. T. H. J. Huisman for chromatographic investigations and Dr. C. Baglioni for the fingerprint analysis and for his advice.

TRANSFER OF CONDITIONED RESPONSES FROM TRAINED RATS TO UNTRAINED RATS BY MEANS OF A BRAIN EXTRACT

By Dr. FRANK ROSENBLATT, JOHN T. FARROW and WILLIAM F. HERBLIN

Cognitive Systems Research Program, Section of Neurobiology and Behavior, Division of Biological Sciences, Cornell University, Ithaca, New York

THREE independent investigations reported during the past year have suggested that learned responses may be transferred from one vertebrate brain to another by means of a brain extract. The first of these, by Fjerdingstad, Nissen and Røigaard-Petersen[1], demonstrated that an intracisternal injection of an extract from the brains of rats trained to run to a signal light facilitated the learning of the same task by naïve rats. It was assumed, in this investigation, that the information-bearing molecule in the extract was RNA.

The second investigation, by Ungar and Oceguera-Navarro[2], utilized an extract from the brains of rats habituated to the sound of a hammer dropping on a metal plate. This extract, injected intraperitoneally into mice, facilitated the habituation of the mice to the same stimulus, as measured by startle responses. These workers suggested a peptide or protein molecule as the active component.

The most recent investigation, by Babich, Jacobson, Bubash, and Jacobson[3], again used an RNA extraction procedure, with an intraperitoneal injection in rats, and the task transferred was that of running to a food cup in a Skinner box in response to the click of a pellet dispenser. The results of this experiment, although again making use of a small number of animals, seemed to be most significant statistically, and the experiment had the further advantage of demonstrating transfer of the learned response without retraining or reinforcement, eliminating the possibility that the effect might involve merely a general sensitization or facilitated learning. The method of preparation and a biuret test performed in these experiments seemed to eliminate protein as a plausible molecule, and it was assumed that RNA was the information carrier. This assumption is in line with the earlier speculation by Hydén *et al.*[4-6] that RNA was a likely candidate for a memory encoding molecule. Alternative models have emphasized the possibility of chemical memory trace mechanisms which would lead to synaptic facilitation, rather than recording the experiential information directly in the form of a molecular code[7-9]. In such a model, RNA changes would merely form part of an induction cycle, leading, for example, to modified membrane proteins and alterations in the 'adhesive codes'[10] governing the synaptic connectivity of specific sets of neurones.

The work recorded here was designed, first, to replicate the results of the previous experiments with a larger number of animals, and, second, to test explicitly the conjecture that RNA might be responsible for information transmission by the brain extracts. The method of Babich *et al.* was used, the only major departure being in the use of a pooled extract from the brains of 20 trained rats in each experiment, rather than one-to-one matching of donors and recipients.

A total of 140 female albino rats was used (supplied by Holtzman, 190–210 g), including 60 donors and 80 receivers. These animals were divided equally between two experiments, the second being essentially a repeat of the first, with slight variations in technique and localization of brain regions employed in the extracts. In each experiment, 20 donors were trained to run to the food cup in the corner of a Skinner box (supplied by Scientific Prototype) in response to the click of the pellet dispenser. Reinforcement consisted of 45-mg Noyes pellets, given intermittently, on about 50 per cent of the clicks. Training was maintained for five days, with a maximum of 200 clicks or 1 h of training per day for the first four days, and 100 clicks on the fifth day. The animals were starved for two days before starting training, and the training methods were copied as nearly as possible from those of Babich *et al.*[3]. Ten untrained donors, in each experiment, were used for the preparation of a control extract. All 30 donors were killed at the same time, by decapitation, and the extract for each group of receivers obtained from the pooled brains of the donors.

Brain extracts were prepared by the RNA extraction method described by Babich *et al.*, except for the variations noted. In all, eight extracts were prepared, as follows.

Extract 1. The midsections (exclusive of frontal regions, cerebellum and brainstem) of the brains of ten untrained rats were utilized. These brain sections were ground with 80 ml. of fine sand in a large cold mortar, with 100 ml. phenol (90 per cent) and 100 ml. cold saline. This resulted in a large volume of liquid in which the brain tissue was very difficult to homogenize. The liquid remained quite thin and was decanted from the sand and centrifuged at 8,000*g* for 20 min at 0–4° C. The aqueous phase (about 40 ml.) was collected, and magnesium chloride was added to bring the concentration to 0·1 M. Two volumes (80 ml.) of cold ethanol were added and the mixture was allowed to stand in the cold for 30 min. The precipitate (presumed to be chiefly RNA) was collected by centrifugation at 35,000*g* for 30 min. The ethanol-water mixture was decanted and the residue dried *in vacuo*. The residue was taken up in 11·5 ml. saline. This solution was used for injection. The RNA concentration in this extract was estimated as 0·172 mg/ml. by determination on a Beckman *DB* spectrophotometer at 260 mμ (total RNA was 1·98 mg). This value, however, may be spuriously high due to a contribution from residual phenol in the extract, which peaks at 264 mμ.

Extract 2. Midsections of the brains of ten of the trained rats were employed. To avoid the difficulty of the first extract, only 10 ml. of phenol and 10 ml. of saline were added to the sand and brains. This resulted in a paste which homogenized easily. The remaining 80 ml. of the 1 : 1 phenol-saline mixture was then added. The remainder of the procedure was identical with that used for Extract 1. The RNA concentration was estimated to be 0·327 mg/ml. (or 3·76 mg total), again with the possibility of some phenol contamination.

Extract 3. The brain tissue used consisted of 10 midsections and the 20 residual portions (frontal and midbrain) from the trained rats. This had been frozen rapidly and stored for 48 h. The total weight was about 25 g. The extraction procedure was the same as for Extract 2, with 200 ml. of the phenol-water solution. The final residue was taken up in 22 ml. saline. The RNA concentration was estimated as 1·31 mg/ml. (or 28·8 mg total).

Extract 4. Half the solution obtained in Extract 3 was used (11 ml.). 1·1 mg of ribonuclease was added, and both Extracts 3 and 4 were incubated at 40° C for 1 h. The solutions were then stored at 0–4° C overnight before injection.

Extract 5. The entire cerebral sections of the brains of ten more untrained rats were employed. The extraction was performed as above, except that the brains were first homogenized, three or four at a time, with about 20 ml. of the saline in a Potter–Elvehjem homogenizer. The remaining 30 ml. saline and 50 ml. phenol were then added together with the sand, and the resulting mixture treated as before. Considerable care was taken in this and following extracts to get rid of all the liquid phase before drying the precipitate, to eliminate possible phenol contamination. In addition, a phenol blank run through the same procedure showed that all detectable traces of phenol had vanished after vacuum drying. The RNA concentration of the resulting extract was 0·52 mg/ml. (5·98 mg total yield).

Extract 6. The cerebellar portions (cerebellum and brainstem) of the brains of the second 20 trained rats were used. The extraction procedure was identical to that used for Extract 5, and the RNA concentration was 0·56 mg/ml. (6·94 mg total).

Extract 7. The cerebral portions of the brains of the second 20 trained rats were extracted by the same method as above, after having been frozen for 48 h. The RNA concentration was 0·42 mg/ml. (average of two determinations), with a total yield of 10·2 mg.

Extract 8. Half of Extract 7 was incubated with RNase by the same procedure as Extract 4. A measurement of the resulting solution at 260 Å indicated the equivalent of an RNA concentration of 0·57 mg/ml. (average of two determinations). The higher concentration obtained in the incubated extracts is an indication that the RNase was effective in breaking up the RNA into nucleotide components. A further test, to make sure the RNase was fully effective, was run by column fractionation on 'Sephadex *G*50' medium. A known RNA sample, used for comparison, gave one peak before incubation with RNase, and a single, distinctly separate peak after incubation. The same separation of peaks was found for Extracts 7 and 8, and it was estimated that residual RNA must have been reduced to something less than half of a per cent of the original content.

The injected animals were divided into eight groups of ten, each group (labelled *A*–*H*) receiving one of the eight extracts. Each rat was injected with 1 ml. of extract, intraperitoneally. Table 1 shows the treatment of the eight injected groups. The first experiment consisted of the training of the first 20 rats, the preparation of Extracts 1–4, and the injection and testing of Groups *A*, *B*, *C*, and *D*. The second experiment consisted of the training of the second group of donors, with the remaining extractions and tests of Groups *E*, *F*, *G*, and *H*. The rats were tested in four sets of 20, the first consisting of Groups *A* and *B*, the second of Groups *C* and *D*, the third of *E* and *F*, and the fourth of *G* and *H*. Each group of 20 was divided at random between the two types of extract employed, and tested by observers who were not informed of the identity of the rats until the tests were completed.

Each of the injected rats was given a total of 30 min in the Skinner box, over the two days prior to injection, and was starved throughout this habituation period. A total of ten clicks from the empty pellet dispenser was given to each rat during this period, and her responses were recorded. In testing the animals, the criteria for administering a stimulus corresponded to those employed by Babich *et al.* Clicks were given after the rat had been in the box for two minutes, and were spaced at least 1 min apart. The animal was required to be facing at least 90° away from the food cup in order to receive a click. Records of the time taken to reach the food cup were kept by means of a stop-watch. For the first experiment, a response was counted if the rat's nose passed within 2 cm of the food cup. For the second experiment, the response criteria were tightened, and responses were counted only if the rat was sniffing directly at the food cup, or had her nose over the rim. This led to a significant reduction in the number of responses counted in the second experiment, but it was hoped that spurious responses would be more effectively eliminated.

Each of the first five test sessions for each rat (after injection) consisted of five unreinforced clicks, response times being recorded as already described here. This was followed by a sixth session with a pellet in the cup at the outset, followed by five reinforced clicks. This was followed by a seventh, unreinforced, session of five clicks. In these last two sessions, the time to pick up the pellet was recorded, and responses were counted only if the rat's nose was over the edge of the food cup. For the first series of runs in Experiment 1, a second observer was employed who counted all approaches of a rat to the food cup, to obtain some measure of total activity. As there was no indication that this total activity measure was any different for controls and experimental groups, this measurement was discontinued in later runs. In the first experiment, each rat was given one pellet of lab chow between sessions 5 and 6; in the second experiment, they were given a pellet of lab chow after session 4.

Table 1. Groups of injected Rats (10 Rats in Each Group)

Group	Injections	RNA dosage (mg)
A	Extract 1 (control)	0·17
B	Extract 2 (trained cerebrum)	0·33
C	Extract 3 (trained whole brain)	1·31
D	Extract 4 (Extract 3 + RNase)	—
E	Extract 5 (control)	0·52
F	Extract 6 (trained cerebellum)	0·56
G	Extract 7 (trained cerebrum)	0·42
H	Extract 8 (Extract 7 + RNase)	—

Table 2. Response Rates of Each Group as a Percentage of Responses within 2, 3, and 5 Sec

Group	Unreinforced tests (1–5)			Reinforced tests (6–7)			Combined tests (1–7)		
	2″	3″	5″	2″	3″	5″	2″	3″	5″

RNase:	1·4	2·2	5·0	8·5	13·0	24·5	3·5	5·3	10 6

Table 3. Numbers of High and Low Rats in Control and Experimental Groups. High Rats have 3 or more Responses within 2 Sec in Exp. 1, or 2 or more Responses within 2 Sec in Exp. 2

Group	No of rats Low	High
A	10	0
B	6	4
C	7	3
D	6	4
E	10	0
F	6	4
G	9	1
H	9	1
All groups	63	17
Controls (*A*, *E*)	20	0
Trained extract	43	17
RNase (*D*, *H*)	15	5

The first test was administered about 4 h after injection, and the following three sessions spaced about 3 to 4 h apart. Session 5 was given the following day, and sessions 6 and 7 within 24 h afterwards.

The principal results of these experiments are presented in Tables 2 and 3. The distribution of fast responses (5 sec or less) seemed to be most indicative of the difference between experimental and control rats. Table 2 shows the percentage of responses within 2, 3, and 5 sec for each group, and for the combined controls, combined 'experimental' groups (*B*, *C*, *D*, *F*, *G*, *H*) and combined RNase groups. The response times for the pre-injection tests (10 clicks per rat) were recorded for the 40 rats used in Experiment 2. This yielded a total of 3 responses (0·75 per cent) within 2 sec, 3 within 3 sec and 11 within 5 sec. It appeared from these data that the injections had 'taken' on some of the rats, but not on others, conceivably due to immunological factors. A 'take' was characterized by a relatively large number of fast responses, typically within 2 sec or less, and was generally brought out quite reliably by the 'retraining' procedure of Sessions 6 and 7. Several of these rats, after eating their first pellet, scarcely missed a response during any of the subsequent ten clicks, wheeling rapidly (within 1 sec) from any starting position, and dashing directly to the food cup. By contrast, records of an exactly similar procedure for the second group of 20 donors, for 5 reinforced and 5 unreinforced clicks at the outset of their training, yielded a total of only 2 responses within 2 sec (1 per cent), and 7 responses within 3 sec. Although these figures agree closely with those of the injected control groups, they have not been treated as additional control data as the degree of starvation was not the same in both cases.

The time taken to recognize and eat their first sucrose pellet appears not to differ significantly for the control and experimental groups. The most sensitive discrimination of controls from experimental animals was found to result from a dichotomization of the injected rats into 'high' and 'low' categories. Since the response criteria were tighter on Experiment 2, slightly different cutting points had to be chosen in each case. For Experiment 1, a 'high' rat is one with a total score of three or more 2-sec responses in the seven sessions, while for Experiment 2 (Groups *E*–*H*) a 'high' rat is one with 2 or more 2-sec responses. These criteria give a total of 17 high rats out of the 80 injected animals, 11 in the first experiment and 6 in the second. The distribution of high and low rats for the different groups and important combinations of these is shown in Table 3. Combining the results of the two experiments, we find that among the 20 controls, there were no 'high' rats, all 17 'highs' being distributed among the 60 animals receiving some form of 'trained' extract. This difference is significant at a level of 0·4 per cent by a Fisher exact probability test[11]. The comparison of the controls with the trained extract rats from Groups *B* and *F*, which were tested at the same time (guaranteeing uniform treatment), gives a significance level of 0·16 per cent. (It should be noted that this is a very conservative test for these data, taking no account of the actual numbers of responses, and making no parametric assumptions.) If the 'retraining' data (sessions 6–7) are neglected, and a criterion of 2 or more 3-sec responses is taken to characterize a 'high' rat, then there are 9 'high' rats from the trained injections, and one from the controls ($P = 0{\cdot}08$). Although these results are clearly significant, they show a weaker effect than that observed by Babich *et al.* with the same training and extraction procedures. The possibility that this difference was due to the use of pooled brain extract instead of 1 : 1 injections has been checked in a subsequent experiment (to be reported in detail in a later publication) with negative results. Some more subtle differences either in training or in extraction procedures must, therefore, be responsible for the magnitude of their effect. The trained cerebellar extract seemed to be as potent as the trained cerebral extract, and the incubation with RNase did not eliminate the effect, even though RNA was shown to be eliminated from the extract. The difference between the combined RNase groups and the controls is significant at 2·4 per cent, and the difference between the cerebellar group and its corresponding control group (Groups *E* and *F*) is significant at 4·3 per cent. No other significant differences were found.

Since the biuret test employed by previous investigators[3] is insensitive to quantities under 1 mg, a more sensitive protein determination, using the Folin–Ciocalteau method[12], was carried out on Extract 7. This showed a concentration of 1·1 mg/ml. in this extract. This result is consistent with the work of Ungar and Oceguera-Navarro[2], who report that their effect is eliminated by chymotrypsin.

These results seem to confirm the possibility of 'memory' transfer by means of a brain extract, for a simple operant response to an auditory stimulus. It appears that the information-bearing molecule is not RNA, but might be a small soluble protein or polypeptide. Subsequent experiments by our group (to be reported later in detail) have shown that a bar-pressing response in a Skinner box can also be transferred, and that the molecular weight of the information-bearing molecule seems to be in the range of 1,000–5,000, as measured by 'Sephadex' fractionation. While consistent with the polypeptide hypothesis, this weight range would exclude any known form of RNA. The appearance of the effect from both cerebral and cerebellar extracts (if verified) argues against sharp localization, but this may be simply a reflexion of the complexity of the task employed, with different types of conditioning being recorded at each level.

We thank Rodman G. Miller for his assistance, and Prof. R. D. O'Brien for the use of his laboratory. This work was supported by the Office of Naval Research, contract *NONR* 401 (40), and U.S. National Science Foundation contract *GK*–250.

REPAIR OF X-RAY DAMAGE TO THE DEOXYRIBONUCLEIC ACID IN *Micrococcus radiodurans*

By Dr. C. J. DEAN, P. FELDSCHREIBER and Dr. J. T. LETT
Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3

THE dose of radiation required to inactivate a cell is determined by the extent of radiochemical damage and the capacity of the cell to restore this damage. While much evidence implicates DNA as the site of the primary radiochemical lesion, several possibilities have been considered to explain why cells such as *Micrococcus radiodurans* exhibit extreme resistance to X-rays[1], including critical structures which require exceptional doses of radiation to be damaged, the possession of intracellular protective agents[2], and the operation of very efficient repair processes[3]. *Micrococcus radiodurans* is also remarkably resistant to the lethal action of ultra-violet irradiation[4], but Setlow and Duggan[5] found that the DNA of this organism, as judged by thymine dimer production, is not particularly resistant to ultra-violet radiation damage and they suggest that the bacterium possesses a very efficient DNA repair system for ultra-violet damage. Furthermore, the ultra-violet action spectrum points to a possible role of deoxycytidine or protein damage in cell inactivation as well as in the delay in DNA synthesis observed at sub-lethal doses[6].

Possession of an intracellular protective agent has been proposed to account for the resistance of *M. radiodurans* to X-rays[2] and support for this hypothesis is lent by the finding that hydroxymercuribenzoate and iodoacetamide—both powerful sulphydryl poisons—enhance the inactivation by X-rays[7–9]. Radiosensitization by iodoacetamide, however, is not due to removal of intracellular —SH prior to irradiation, and the possibility has been considered[3] that these sensitizers act by enhancing the X-ray inactivation of the metabolic repair processes in radio-resistant organisms.

M. radiodurans shows 100 per cent survival following irradiation with 110 krads of X-rays under anoxia, a dose which has been shown to produce considerable physico-chemical damage to the DNA of *E. coli B/r* (ref. 10). Until recently it has not been possible to determine the nature and extent of the *in vivo* X-ray damage to the chromosome of *M. radiodurans* since no suitable method for isolation of the DNA has been available. The culture fluids of *Streptomyces albus G* have been shown to contain a number of bacterial cell-wall degrading enzymes[11,12], and one of these, the '*R*1 fraction'[13], was found to be lytic towards *M. radiodurans*[14]. This observation has led to the development of a suitable procedure for isolation of DNA from this bacterium. This communication describes some of the changes which occur in the DNA of *M radiodurans* following X-irradiation.

Radiosensitivity of M. radiodurans DNA in vivo. Exponentially growing cells of *M. radiodurans* were obtained by diluting a 14-h-old culture in TGY medium (0·5 per cent tryptone, 0·1 per cent glucose, 0·3 per cent yeast extract) three-fold with fresh medium and incubating in shake culture at 30° C until the optical density at 650 mμ reached a value of 0·8. The culture was chilled, the cells collected in a Sharples centrifuge, washed once in 0·04 M veronal buffer *p*H 8·6 and resuspended in the same buffer at a concentration of approximately 5×10^{10} cells/ml. Stirred samples were irradiated at 4° C under nitrogen with 220 kV X-rays at a dose rate of $1{\cdot}1 \times 10^4$ rads/min. A survival curve for cells irradiated under these conditions is presented in Fig. 1 and shows that no cell inactivation occurs at doses below 0·5 Mrad.

To extract the DNA, 20-ml. samples of the suspension in veronal buffer were incubated with 5 mg *Streptomyces* '*R*1 fraction'[13] for 15 min at 30° C. This suspension was then cooled in ice and 10-ml. samples irradiated at 4° C. Immediately after irradiation, 4-ml. samples of this suspension were added to a solution containing 50 ml. TGY medium, 15 ml. 0·2 M citrate-phosphate buffer *p*H 5·6 and 13 ml. 20 per cent sodium dodecyl sulphate. After incubation for 15 min at 30° C to initiate lysis the samples were left to stand at room temperature until dissolution of the cells was complete (about 1–2 h). The clear, highly viscous solution was made 1 M with respect to sodium chloride and the sample shaken gently at room temperature for about 12 h. After centrifugation at 10,000*g* for 10 min to remove precipitated protein and polysaccharide, an equal volume of 2-ethoxyethanol was added slowly to the supernatant to precipitate the DNA. The fibrous material was collected, rinsed briefly in absolute ethanol and redissolved in 30 ml. of M/100 sodium chloride. 3 ml. RNase solution (4 mg/100 ml.) were added and the samples incubated at 25° C for 4 h. After addition of 1·5 ml. of 20 per cent sodium dodecyl sulphate and 8 ml. of 5 M sodium chloride, the samples was shaken gently for 15 min and any insoluble material was removed by centrifugation at 15,000*g* for 10 min. The DNA was precipitated by addition of an equal volume of 2-ethoxyethanol and the fibres washed twice in absolute ethanol, once in acetone and air dried. The yield of DNA was 50–80 per cent. The treatment with *Streptomyces* '*R*1 fraction' alone caused no cell inactivation during a period of 2 h and the X-ray survival curve for enzyme treated suspensions is identical to that shown in Fig. 1.

The molecular weight of the DNA was estimated by measurement of its intrinsic viscosity (η) in a Couette viscometer and its sedimentation coefficient $S_{20,w}$ in the Spinco model *E* ultracentrifuge with ultra-violet optics. From these measurements it is possible to determine the nature of the changes in macromolecular structure following X-irradiation[15]. Fig. 2 shows the reciprocal values of the intrinsic viscosities of DNA samples extracted

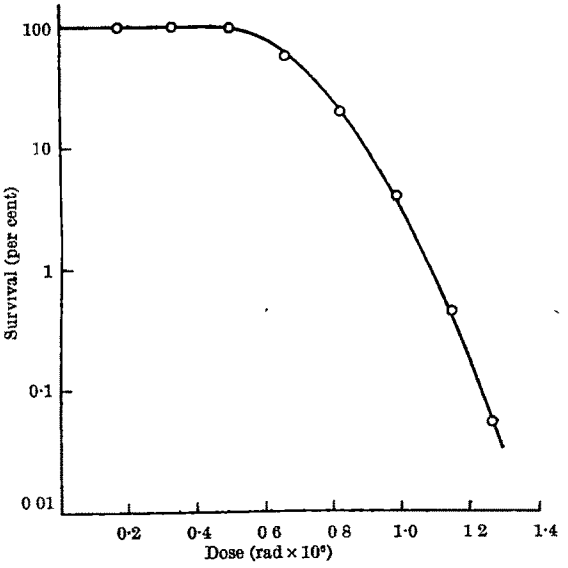

Fig 1. Survival curve of *M. radiodurans* irradiated under anoxia

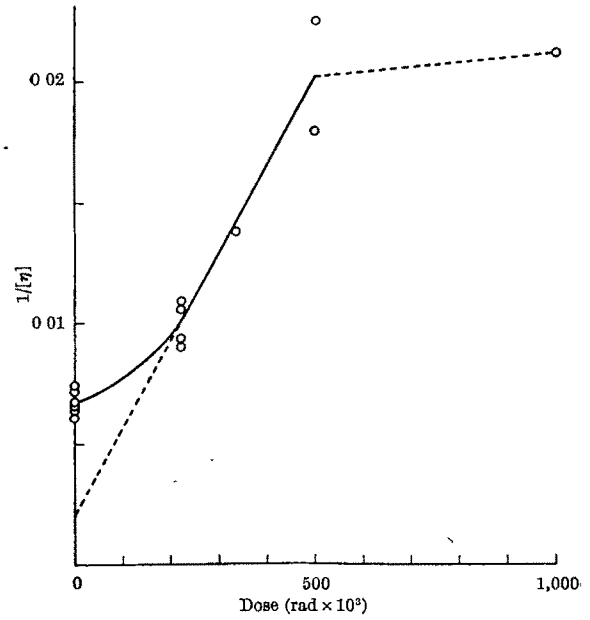

Fig. 2. Effect of X-rays *in vivo* on the reciprocal intrinsic viscosity of *M. radiodurans* DNA

from cells immediately after irradiation with doses of 220, 330, 495 and 990 krads. The results show that there is a considerable decrease in viscosity of the irradiated samples and that the extent of the decrease is dose dependent.

When DNA is irradiated with sparsely ionizing radiations *in vitro*, the change in its intrinsic viscosity is a direct measure of the number of scissions in the twin helix (double breaks) caused by a given radiation dose[15]. The physico-chemical changes observed in the DNA extracted from *M. radiodurans* indicate that over a limited dose range a similar relation obtains as in Table 1.

Table 1. Viscosity of DNA isolated from X-irradiated Cells during Post-irradiation Incubation at High Cell Concentrations (about 5 × 10⁸/ml.)

Dose (krads)	Incubation time	$S_{20,w}$	$[\eta]$ (dl./g)	% Yield DNA	Molecular weight[26] calc. from $[\eta]$	Molecular weight[26] calc. from $S_{20,w}$
0	0	27·2	151	77	13·7 × 10⁶	13·1 × 10⁶
220	0	24·2	92	55	8·8 × 10⁶	9·5 × 10⁶
0	4 h at 30° C	—	150	73	—	—
220	4 h at 30° C	—	93	60	—	—

The plot of the reciprocals of the intrinsic viscosities of *M. radiodurans* DNA with increasing cellular X-ray dose is shown in Fig. 2 and it can be seen that linear extrapolation gives a much higher zero dose intrinsic viscosity than the actual experimental controls. The behaviour above 500 kr. may indicate the presence of cross-linking[15].

DNA of high molecular weight is very susceptible to hydrodynamic shear[16]. A given shear rate will reduce all molecules above a certain size to a lower size distribution, but longer shearing at the same rate will have no further effect. In a similar fashion different shear rates will cause plateaux at different size distributions[17]. If the DNA extraction procedures utilized for *M. radiodurans* impose approximately constant shear rates this would explain why the function in Fig. 2 does not extrapolate to the control viscosity because on this basis the rate of shear will reduce control and irradiated DNA alike to a limiting size, unless the irradiation alone reduces the molecular weight below this limit. Thus the control viscosities so far as irradiation is concerned would not be the 150 dl./g measured experimentally, but could be nearer the 500 dl./g indicated by the extrapolation in Fig. 2.

The linear portion of the graph in Fig. 2 suggests that *M. radiodurans* DNA is about 25 per cent more resistant to X-ray-induced double breaks than the DNA of *E. coli B/r* (ref. 10) when irradiated *in vivo*. At a sensitivity of 140 eV per number-average double break the *M. radiodurans* DNA is about six times less resistant than salmon and herring sperm DNA irradiated *in vitro*[15]. The apparent increased radiosensitivity of DNA *in vivo* may be due to a large contribution by indirect action[18], or to 'energy transfer' from the proteins associated with the DNA[19]. However, it can also be explained as another result of hydrodynamic shear since irradiation of DNA also causes single breaks, that is, scission of only one chain of the twin helix[15]. These single breaks constitute points of weakness in the DNA molecule and the intact strand may rupture at these points under shear rates which would not be expected to produce double breaks in an undamaged molecule, with the net result of more double breaks than were actually caused by irradiation. If the X-ray sensitivities of herring and salmon sperm DNAs irradiated *in vitro* represent the true situation occurring in *M. radiodurans*, then this would require that at least five single breaks are produced for every double break in the bacterial DNA on X-irradiation. The extrapolation in Fig. 2 is very uncertain because both the types of shearing damage discussed above can occur at the same time and there is also no reason to expect the intrinsic viscosity to be linearly related to the molecular weight above molecular weights of 20×10^6. All that can be said is that the true control molecular weight is very large, perhaps encompassing all the DNA in the cell. There can be no doubt, however, that the DNA of *M. radiodurans* has sustained considerable damage at doses where the cells exhibit 100 per cent survival. If the DNA of *M. radiodurans* is contained in a single chromosome as described for *E. coli*[20], then it must possess the capacity for the repair of double breaks in the twin helix.

Post-irradiation incubation. Cells were grown and irradiated as described and then diluted into fresh medium and incubated at 30° C with shaking. Incubation was examined at two concentrations, namely, *c.* 4×10^9 cells/ml. and 2×10^8 cells/ml. At the former concentration no cell growth would be expected while at the latter, unirradiated cells will undergo exponential growth for at least 3 h. During incubation, samples of the cultures were taken for determination of optical density at 650 mμ, DNA content by the method of Burton[21], and acid insoluble protein by the procedure of Lowry *et al.*[22]. When cells which had been irradiated to a dose of 220 krads were incubated at the higher cell concentration in fresh medium no change in either DNA or protein content was observed during a 4-h incubation period at 30° C. Neither was there any detectable alteration in the viscosity of the DNA extracted from cultures during incubation (Table 1) suggesting that under non-growth conditions no degradation, synthesis, or repair of DNA occurs.

Cultures of unirradiated cells incubated at the lower initial cell concentration show an exponential increase in turbidity, DNA and protein content with a doubling time of 120 min. Cells irradiated to doses of 220, 330 and 495 krads, however, show no net increase in DNA during the early period of incubation (Fig. 3*a*). After this lag, the length of which is dose dependent, DNA synthesis commences at a rate at least equal to that of the control culture. The cells irradiated to 495 krads show a small but significant decrease in DNA content during the period before DNA synthesis starts, indicating that some degradation of the DNA occurs during this time. Both the turbidity and protein content (Fig. 3*b*) of the irradiated cultures increase during the initial period of incubation, but at a rate which is both slower than the control and also dependent on the dose of radiation received. Pronounced degradation of DNA during post-irradiation incubation has been reported in *E. coli* and *E. coli B/r*, but only after doses of X-rays which are both lethal and an order of magnitude less than those described in the present communication. At doses where survival was

50 per cent or more, neither DNA degradation nor delay in synthesis was observed[23,24].

Clearly, at doses of X-rays which cause no cell inactivation, profound changes occur in the metabolic activity of *M. radiodurans*, the most remarkable being the delay in DNA synthesis, a phenomenon also observed following ultra-violet irradiation[5]. Since no increase in cell number occurs until after DNA synthesis resumes, we may conclude that during this delay part or all of the lethal damage in the DNA is repaired. While evidence of synchronized growth is seen in the irradiated cultures, signs of partial synchrony at least can be seen in the unirradiated cultures as would be expected for cell cultures held at the high concentration and low temperature for the 30–60 min required for irradiation.

Repair of the X-ray lesion in DNA. It was found that during post-irradiation growth the cells repaired the partial degradation of the cell wall resulting from treatment with the *Streptomyces R*1 fraction so that cells no longer lysed on treatment with dodecyl sulphate. The DNA isolation procedure was therefore modified. After harvesting from the post-irradiation growth media, the cells were resuspended in 0·04 M veronal buffer *p*H 8·6 at a concentration of *c.* 10^{10} ml. and treated with '*R*1 fraction'. The remaining steps in the isolation procedure were then carried out as described previously.

Marked changes in both the viscosity and extractability of the DNA occur during post-irradiation incubation under growth conditions. After approximately 2 h incubation, the DNA extracted from cells which had received 220 krads of X-rays gave the same viscosity as that from unirradiated cells (Table 2). DNA extracted from cells incubated for 1 h, however, showed a lower viscosity than the zero time irradiated samples, indicating that some degradation of the DNA occurs during the 'lag period'. During the 'lag period' considerable difficulty was encountered in preparing samples of fibrous DNA by the standard technique from cells which had been irradiated to doses of 330 and 495 krads. After DNA synthesis had commenced, samples of fibrous DNA could again be prepared, and it is apparent from Table 2 that even after doses of 330 and 495 krads the viscosity of the DNA had returned to that of the control value. The inability to prepare samples for viscosity measurement from heavily irradiated cells during the early part of the repair process is due, in part, to the non-precipitability of the DNA in 2-ethoxy ethanol. This loss in DNA precipitability does not seem to be due to extensive denaturation because the buoyant density of DNA extracted from an irradiated cell lysate by caesium chloride equilibrium density centrifugation is the same whether the cells were taken immediately after irradiation, in the middle of the post-irradiation lag phase or after the onset of DNA synthesis. The data would therefore indicate a further reduction in the molecular size of the DNA. It is also possible that during this time part of the DNA is rendered non-extractable because of chemical combination with protein such that the buoyant density is not altered in caesium chloride.

Table 2. CHANGES IN VISCOSITY (AS PERCENTAGE OF CONTROL) OF DNA ISOLATED FROM X-IRRADIATED CELLS DURING POST-IRRADIATION INCUBATION AT LOW CELL CONCENTRATIONS (ABOUT 2 × 10^8 CELLS/ML. INITIAL CONCENTRATION)

Dose (krad)	(η) % control at time (h) 0	1	1·5	2·0	2·5	3·5	4·0	4·5
220 (i)	69·0	60·5	—	99·0	—	—	—	—
220 (ii)	65·5	48·5	—	91·0	—	100	—	—
330	49·5	—	*	—	69·0	—	96·0	—
495	33·0	—	—	—	*	—	—	95·0

— No sample taken * No fibrous DNA could be prepared at these times (see text)

It is quite clear from these results that *M. radiodurans* possesses a most efficient DNA repair system which is even capable of restituting 'double breaks' in the twin helix. The decrease in molecular size seen during the early part of the repair process indicates that damaged regions of the DNA are being removed. Confirmation of such an excision process has been found following X-irradiation of cells of *M. radiodurans* labelled in their DNA with tritiated thymidine. Measurements of tritium activity of cold perchloric acid (PCA) extracts of cells and also of the media suggest that tritium label passes first into the PCA soluble fraction and then into the medium (Fig. 4). The excision process begins immediately on incubation and the quantity released reaches its maximum at the time when DNA synthesis commences. Thus during the 'lag period' when no DNA synthesis is observed, excision of damaged regions of the DNA is occurring.

Four possible schemes for the repair of X-ray damaged DNA in *M. radiodurans* may be considered, namely: (1) Excision, followed by restitution, followed by synthesis; (2) excision, followed by restitution and synthesis together; (3) excision and restitution together, followed by synthesis; (4) all three together.

In all four cases the term 'excision' may include removal of areas adjacent to the damaged sites, as has been envisaged by Boyce and Howard-Flanders[25] following ultra-violet damage.

The release of labelled material reaches its maximum before the onset of DNA synthesis; therefore, these two processes would seem to be divorced from one another. This argues against scheme 4. While labelled material is being released from the cells the amount of DNA estimated by the Burton method also drops, and while it is not possible at present to compare accurately the relative losses it is evident that more than 75 per cent of the excision loss is not restituted prior to the onset of synthesis proper. This argues against schemes 1 and 3. If restitution is not substantially complete before the onset of synthesis, the DNA might be expected to show symptoms of its unrestituted state. This may explain

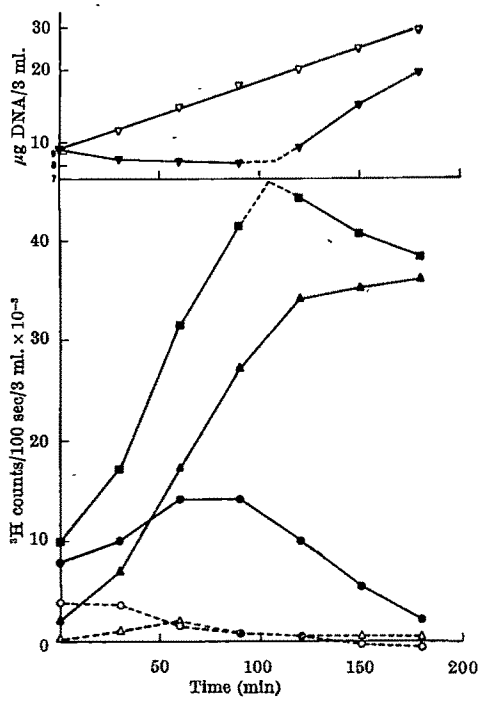

Fig. 4. The release of tritium activity from the DNA of cells given 330 kr. of X-rays, on post-irradiation incubation under growth conditions in TGY medium supplemented with cold thymidine. *a*, Into PCA soluble fraction (○●); *b*, into medium (△▲); *c*, total counts (■). Also shown is the total PCA insoluble DNA content measured by the Burton method. Open symbols are control and closed symbols are irradiated samples. Total activity released 13·6 per cent (of DNA); maximum loss in activity from DNA 14 per cent; maximum loss in DNA by Burton method 12 per cent

why the difficulty in extracting the DNA from lysates of irradiated cells increases during the period of excision, reaches a maximum prior to the beginning of DNA synthesis and then decreases as DNA synthesis proceeds. Once the irradiated cell suspension has doubled its initial DNA content the DNA is indistinguishable, by the physico-chemical methods employed, from control DNA. Most of the evidence would therefore point to scheme 2, and if this is the case then a DNA polymerase may possess the ability to effect both restitution and synthesis.

More difficulty is experienced in explaining the repair of the physico-chemical damage suffered by the DNA on biological grounds. From the interpretation given earlier for the change in molecular size of the DNA on irradiation (Fig. 2) it follows that if the bacterial DNA is all in one piece, and shearing is excluded, the effect of 330 kr. of X-rays will be to cause several hundred scissions of the twin helix (double breaks)—quite apart from single breaks and other damage—and in addition, more than 10 per cent of the DNA components will have been excised from the DNA before the onset of restitution and synthesis. Yet, by the time that the irradiated suspension has doubled its initial DNA content, all these scissions of the twin helix will have been repaired. Either the nucleoprotein structural proteins and/or RNA must play a very important part in maintaining the DNA template or else *M. radiodurans* can tolerate errors in its genetic code and still appear unchanged so far as currently available biological parameters are concerned.

While the restoration of X-ray induced DNA damage in cells of *M. radiodurans* is clearly of importance in terms of the survival of the cells, it cannot be stated with certainty at the present time that cell death occurs because some of the DNA damage is not repaired. Moreover, the restoration of radiation damaged DNA may represent but a part of the capacity of this extraordinary micro-organism for the restoration of cellular damage.

We thank Dr. P. Alexander for his advice, Dr. J. M. Ghuysen for a gift of *Streptomyces* '*R*1 fraction' and Dr. P. Edwards for making the sedimentation measurements. We also thank Mr. A. Smith, Mr. T. Bryant and Miss V. Dagnall for their assistance.

EVALUATION BY RADIOIMMUNOASSAY OF FACTORS CONTROLLING THE SECRETION OF PARATHYROID HORMONE

Intravenous Infusions of Calcium and Ethylenediamine Tetraacetic Acid in the Cow and Goat

PREPARATION of purified bovine parathyroid hormone (PTH) has permitted more definitive characterization of its chemical and immunological properties, as well as its physiological behaviour[1]. In 1963, Berson, Yalow, Aurbach, and Potts[2] reported the development of a specific and sensitive radioimmunoassay for the bovine hormone. In principle, this technique was similar to the methods developed for the measurement of insulin and growth hormone[3], and depended on the inhibition by unlabelled hormone of the binding of hormone labelled with iodine-131 to specific antibody. With recent improvements in the sensitivity of the assay, particularly the use of non-equilibrium conditions[4], it has been possible to measure reproducibly the concentration of PTH in normal bovine plasma and perform a number of physiological studies concerning the regulation of hormone secretion[5].

Bovine PTH was purified by gel filtration[6] and ion exchange chromatography[1]. This highly-purified product was labelled with iodine-131 (IsoServe Corporation, Cambridge, Massachusetts) by the method of Hunter and Greenwood[7] and was used as the test antigen. Antibody produced by repeated injections of a crude hormone preparation into guinea-pigs was used at a final dilution of 1/300,000 in the assay[2].

Parathyroid hormone in bovine or caprine plasma was measured by a modification of the method of Berson *et al.*[2]. In the non-equilibrium assay, unlabelled hormone or unknown plasma was pre-incubated at 4° C with antibody for 4–5 days; labelled hormone was then added to the mixture for 24–48 h. This technique offered several advantages: (1) the assay was more sensitive, since there was a greater decrease in bound to free ratio for a given amount of unlabelled hormone; (2) the shortened incubation period markedly decreased radioactivity 'damage'[3] and allowed the use of labelled hormone of high specific activity (700–1,000 μc./μg); (3) the binding of unlabelled hormone was facilitated by keeping the concentration of antibody greater than the final dilution (1/300,000) during the pre-incubation phase. With these specific improvements, concentrations of hormone in normal unextracted bovine plasma could easily be measured at a 1/5–1/10 dilution, and absolute amounts of hormone as small as 10 μμg could be detected.

Samples of jugular venous blood were obtained from normal cows under control conditions and during infusions designed to alter plasma calcium concentration. Disodium EDTA or calcium chloride was administered by intrajugular catheter to conscious animals, while periodic samples for calcium determination and immunoassay were obtained from the other jugular vein. Plasma calcium was measured by a modification of the EDTA method[8], the standard deviation being ±0·1 mg/100 ml. Concentrations of calcium in plasma were consistently 0·1–0·2 mg/100 ml. greater than similar measurements in serum, but the results of immunoassay were not significantly different. Bovine plasma was routinely assayed in duplicate at a dilution of 1/5, the standard deviation being ±0·065 mμg for concentrations less than 1·0 mμg/ml. and ±0·171 mμg for concentrations of 1·0–6·0 mμg/ml.

Similar infusions were administered to goats anaesthetized with methoxyfluorane through an endotracheal tube. Solutions of calcium gluconate or disodium EDTA were infused via a femoral vein, and jugular venous samples were obtained periodically for measurement of calcium and PTH concentration.

Initial investigations of the cross-reactivity of purified bovine PTH and the endogenous hormone in bovine plasma indicated a reaction of complete identity (Fig. 1). Likewise, there was excellent cross-reactivity between endogenous caprine hormone and purified bovine PTH. While this reactivity was not complete, it was sufficient to permit measurement of PTH concentration in normal caprine plasma at a 1/5–1/1 dilution.

The concentration of PTH in the plasma of 24 normal cows varied from 400 to 1,800 μμg/ml., with a mean of 1,070 (Fig. 2). There was a reciprocal relationship between plasma calcium and the concentration of PTH in the normal animal; this relationship was statistically significant with a correlation coefficient of −0·6.

Infusions of calcium chloride, with corresponding elevation of the plasma calcium, consistently decreased the measureable concentration of hormone in peripheral bovine plasma. This is shown in Fig. 3, where gradual elevation of plasma calcium was associated with a marked reduction in the concentration of PTH. Two hours after beginning the infusion, hormone was not detectable, and even 5 h after the infusion, PTH concentration had not returned to normal. In three different experiments, elevation of blood calcium to 14 mg/100 ml. was accompanied by a complete disappearance of measurable hormone (less than 100 μμg/ml.).

With prolonged infusions of disodium EDTA in two animals (Fig. 4), a decrease in plasma calcium was associated with: (1) a marked and sustained increase in the concentration of PTH; (2) elevation of PTH concentration to three to four times the control value during maximal stimulation; (3) persistence of increased concentrations of hormone despite a prolonged hypocalcaemic stimulus (20 h in one animal and 36 h in the other).

The reciprocal relationship between calcium and PTH concentration was shown more vividly when alternate infusions of calcium, EDTA, and calcium were administered (Fig. 5). Despite the constant rate of fall in plasma calcium with EDTA from 14·5 to 6·1 mg/100 ml., there was no real rise in PTH concentration until the plasma calcium was less than 10 mg/100 ml. In addition, stimulation of the gland with EDTA following suppression with calcium (Fig. 5) produced a smaller increase in PTH

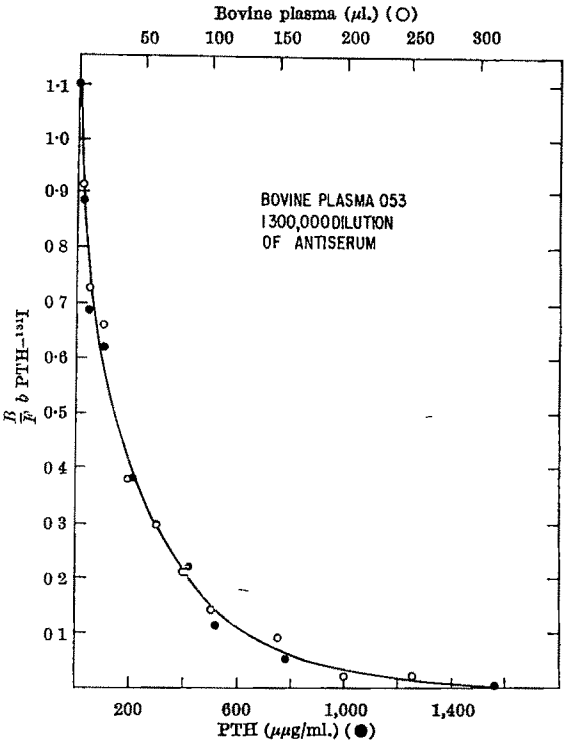

Fig. 1. Standard curves obtained with a purified preparation of bovine PTH (closed symbols, μμg/ml.) and with aliquots of bovine plasma (open symbols, μl. of plasma added to total incubation mixture of 0·5 ml.). The curves through the two sets of points are identical, suggesting a reaction of complete identity between the purified preparation and endogenous hormone in bovine plasma

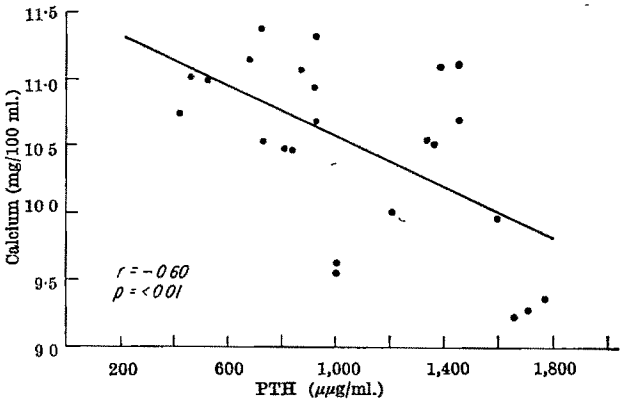

Fig. 2. Distribution of PTH concentration in 24 normal animals. Each assay point represents duplicate determinations in two separate assays (the mean of four values). There is a statistically significant inverse correlation (*P* value less than 0·01) between calcium and PTH concentration in normal animals

concentration than did stimulation without prior administration of calcium (Fig. 4).

The role of calcium ion in the regulation of PTH secretion was also studied during normal lactation and during the syndrome of parturient paresis (or 'milk fever'). Mild physiological hypocalcaemia accompanying the onset of normal lactation (about 8 mg/100 ml.) was frequently

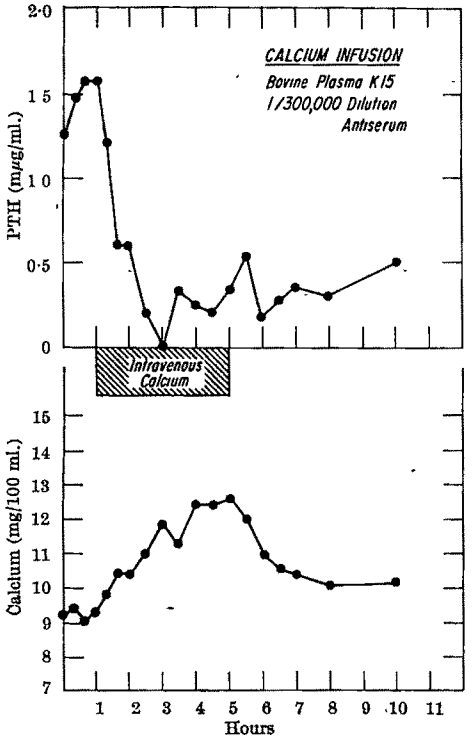

Fig. 3. The effect of a 4-h infusion of calcium chloride (99·6 m.equiv./h) on plasma PTH and calcium concentration in the cow

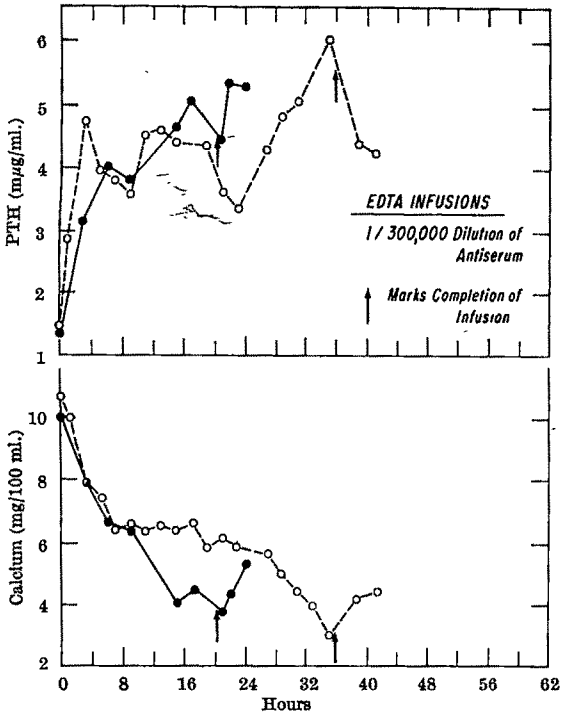

Fig. 4. Infusions of disodium EDTA in two normal cows for 20·5 h (closed symbols, 40 m.equiv./h) and 36 h (open symbols, 57·5 m.equiv./h), respectively; the effects on plasma calcium and PTH concentration are shown. Arrows mark the end of each infusion. Of note is the continued stimulation of PTH production despite the prolonged hypocalcaemic stimulus

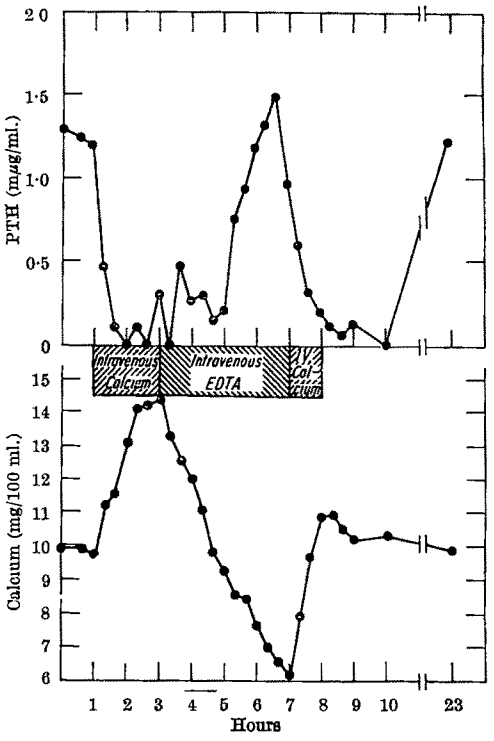

Fig 5. Concentrations of PTH and calcium in bovine plasma in response to alternate infusions of calcium chloride (196·4 m equiv./h), disodium EDTA (115 m.equiv /h), and calcium chloride (196·4 m.equiv./h)

associated with an increase in PTH concentration to two to three times normal. In addition, animals with parturient paresis, a syndrome characterized by marked hypocalcaemia and flaccid paralysis during the postpartum period, showed elevated concentrations of PTH (similar to the concentrations produced by maximal stimulation of the gland with EDTA).

Parathyroid hormone in normal caprine plasma was measured in conjunction with parallel experiments involving perfusion of the isolated superior parathyroid gland of the goat[9]. Variation of the plasma calcium concentration by alternate infusions of EDTA and calcium produced changes in PTH concentration (Fig. 6) which fully corroborated the findings with bovine plasma and permitted direct correlation with the results of isolated parathyroid gland perfusion.

It is reasonable to assume that there is a close correlation between the estimates of PTH concentration obtained by immunological methods and the actual content of biologically active hormone in plasma. The evidence in favour of this approach, as well as the sources of potential error, has been extensively discussed[3,10]. The results reported in this and the accompanying article[9] at least satisfy empirical criteria; the changes in hormone concentration follow the pattern predicted by earlier investigations[11–14] of hormone secretion during physiological variations in plasma calcium. In addition, evidence is provided from isolated gland perfusions in a sheep and goats that the changes in PTH concentration in peripheral plasma are due to actual alterations in the secretion rate of hormone and not merely to changes in its distribution, excretion, or rate of destruction[9].

It is generally believed that the concentration of ionized calcium in the blood directly controls the secretion rate of PTH. Production of parathyroid hyperplasia by diets low in calcium[11], perfusion investigations by Patt and Luckhardt[12] and Copp and Davidson[13], and the *in vitro* investigations of parathyroid cells by Raisz[14] all provide evidence to support this hypothesis. With the use of a sensitive assay to detect PTH in plasma, it has been possible to confirm directly the control of hormone secre-

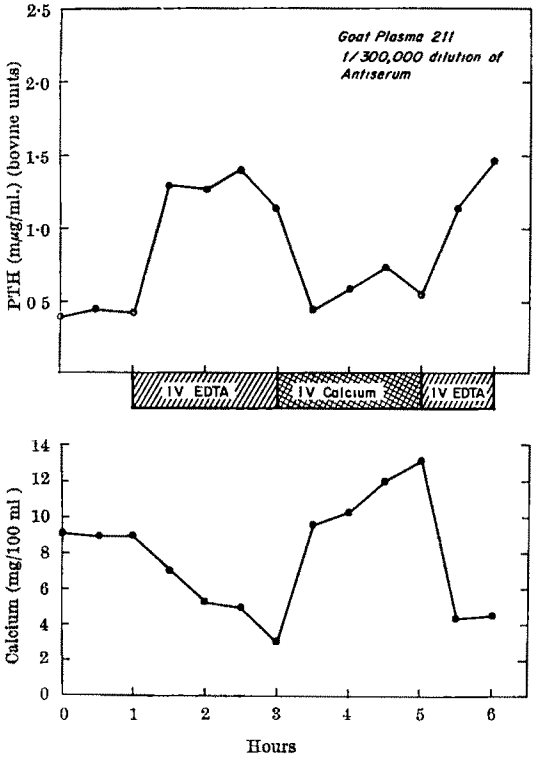

Fig. 6. Concentrations of PTH and calcium in caprine plasma in response to alternate infusions of disodium EDTA (6·44 m.equiv /h), calcium gluconate (9·5 m.equiv /h), and EDTA (6·44 m.equiv./h)

tion by blood calcium. In addition, the presence of an inverse correlation between calcium and PTH in the normal animal suggests that the hormone is being continuously secreted, and that it is under the fine and precise control of blood calcium level[15,16].

With maximal suppression or stimulation of the gland, peripheral hormone concentrations may vary from undetectable values (less than 0·1 mμg/ml.) to 6·0 mμg/ml. The normal range in the animals so far examined has been between 0·4 and 1·8 mμg/ml. Severe hypocalcaemia associated with parturient paresis produced the same increase in PTH concentration noted after maximal stimulation with EDTA, suggesting that an absolute defect in hormone secretion is not the cause of this disorder. An increase in PTH concentration during hypocalcaemia in the cow was thus directly demonstrated without the necessity of administering EDTA acutely to lower plasma calcium.

The maintenance of blood calcium in its narrow homoeostatic range is a highly complex process. It seems clear that changes in PTH secretion play a major part in this homoeostasis, but the interrelationships of PTH, thyrocalcitonin[17], and/or possible hypocalcaemic factors from the parathyroid gland[15] remain to be elucidated. The work recorded here indicates that changes in PTH concentration may appear as rapidly as 20 min after starting an infusion of calcium or EDTA. The diminished response to EDTA stimulation after previous infusion of calcium may reflect a delay in the restoration of hormonal synthesis following suppression of the gland. Preliminary results by the immunoassay method also suggest that magnesium acts like calcium in suppressing PTH secretion[9,18], and that plasma phosphate only indirectly affects PTH secretion by influencing the concentration of ionized calcium in the blood[18].

We thank Dr. Solomon A. Berson for his advice, and Dr. Rosalyn S. Yalow for developing and extending the use of the immunoassay for parathyroid hormone. We also thank Dr. David Kronfeld and Dr. Jesse Roth for their advice. Perfusion of the Isolated Parathyroid Gland of the Goat and Sheep

The investigations of Sherwood *et al.*[1] provide direct evidence from intravenous infusions of calcium and EDTA in the cow and goat that the concentration of parathyroid hormone (PTH) in peripheral plasma varies inversely with blood calcium. The development of techniques for perfusing the isolated superior parathyroid gland of the goat or sheep[2,3] and the strong degree of cross-reactivity between bovine and caprine hormone[1] permitted the direct measurement by radio-immunoassay of the concentration of PTH in the venous effluent of the perfused gland[4]. Variations in the amount of hormone leaving the gland undoubtedly reflect alterations in its rate of secretion; direct assessment of the factors which influence hormone secretion is thus made possible.

(*A*) *Acute Experiments.* Three 12-month-old Nubian Cross female goats, weighing 25–39 kg, were used for the perfusion investigations. The operative procedure was carried out under methoxyfluorane/oxygen closed circuit anaesthesia. Via a midline incision, both thyroid lobes containing the inferior parathyroid glands were removed. The arterial supply and venous drainage of the left superior parathyroid were identified; they were usually in common with those of the left apical lobe of the thymus. The external maxillary artery and vein and the left femoral artery were catheterized with silicone elastic tubing (external diam. 2·1 mm, internal diam. 1·0 mm). Except for those vessels related to the parathyroid and

thymic lobe, all branches of the left carotid artery and jugular vein were ligated between the levels of catheterization and the ligated left superior thyroid artery and vein[2]. Thus, the blood supply to, and drainage from, the left superior parathyroid gland could be isolated from the general circulation by clamping the carotid artery and jugular vein caudal to the points of emergence of the parathyroid vessels. The left apical lobe of the thymus, which contained the left superior parathyroid gland, was separated from the remainder of the thymus. The right superior parathyroid was not disturbed.

After the goat was treated with heparin (250 units/kg initially, then 125 units/kg every 2 h), the left parathyroid gland was perfused with blood of controlled calcium concentration, as described by Care *et al.*[3]. Parathyroid venous blood was obtained via the catheter in the external maxillary vein, after the left jugular vein had been clamped caudal to its junction with the parathyroid vein. The plasma calcium concentration in the perfusate was varied over a wide range (0–13·8 mg/100 ml.) by the addition of either disodium EDTA or calcium gluconate, in 0·9 per cent saline. In two experiments the gland was perfused with blood containing a high concentration of magnesium (2·8–3·7 m.equiv./l.).

The flow-rate of perfusate in the afferent and efferent vessels was measured; they should be equal when satisfactory surgical isolation of the parathyroid *in situ* has been achieved. The concentrations of calcium (by a modification of the method of Hill[5]) and parathyroid hormone (by a modification[1] of the method of Berson *et al.*[4]) in parathyroid venous plasma were determined at suitable intervals. Plasma magnesium was measured by flame photometry[6]. At the end of each gland perfusion, indian ink was added to the perfusate and the perfused gland excised for histological examination to ensure that the parathyroid gland had, in fact, been perfused.

(*B*) *Conscious Animal.* A gland perfusion was performed in one 18-month-old Herdwick sheep (28 kg). The operative procedure, similar to that already described here, was performed under aseptic conditions on the day preceding the parathyroid perfusions. The carotid artery caudal to the parathyroid vessels, with its branches ligated, was placed in a skin tube for ease of temporary occlusion during the gland perfusion. The jugular vein could be occluded with a 2/0 mersilene snare placed caudal to its junction with the parathyroid vein when collection of parathyroid venous blood was required.

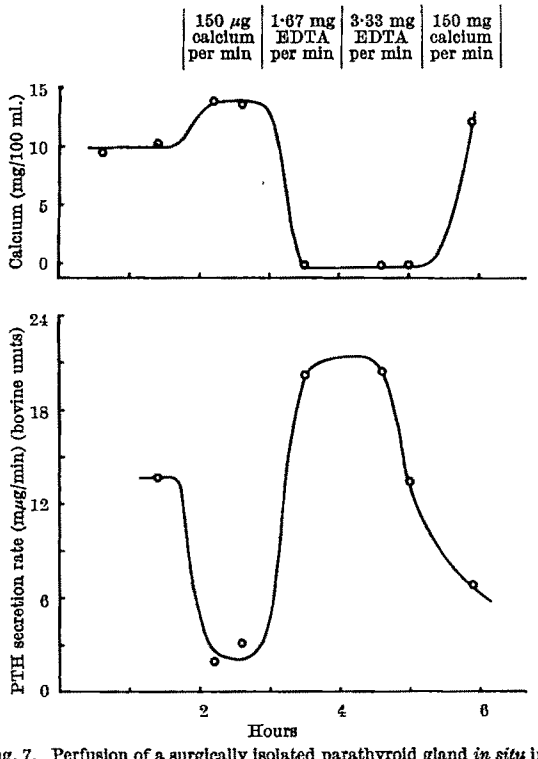

Fig. 7. Perfusion of a surgically isolated parathyroid gland *in situ* in an anaesthetized goat The thyroid and inferior parathyroid glands were removed. Secretion rate of PTH varied inversely with changes in plasma calcium concentration. Blood flow through the gland was maintained at 2·7 ml./min

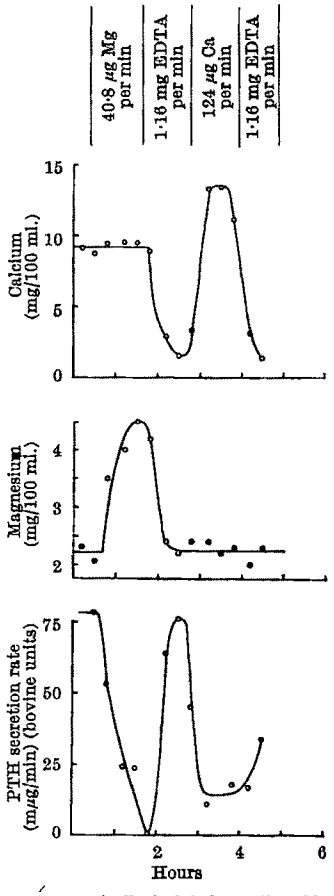

Fig. 8. Perfusion of a surgically isolated parathyroid gland *in situ* in an anaesthetized goat. The thyroid and inferior parathyroid glands were removed. Blood flow through the gland was maintained at 2·7 ml./min. The effects of hypermagnesaemic, hypocalcaemic or hypercalcaemic perfusion on PTH secretion are depicted

The isolated parathyroid gland was perfused for 1·8 h with hypercalcaemic blood, and several parathyroid venous blood samples were collected, some of which were assayed for PTH.

The immunological similarity of bovine and caprine hormone has already been described[1]. Similar cross-reactivity over the most sensitive portion of the standard curve was also observed between bovine and ovine PTH.

The influence of plasma calcium on the secretion of PTH by the perfused gland is shown in Fig. 7. Perfusion of the gland with hypercalcaemic blood (14 mg/100 ml.) caused a marked suppression of PTH secretion to 20 per cent of the initial value. Subsequent perfusion with EDTA resulted in a stimulation of hormone secretion which could easily be suppressed with a second perfusion of calcium. The secretory rate changed rapidly in response to calcium fluctuations, alterations in hormone concentration being evident within 20 min after the calcium concentration of the perfusate was altered[1]. Changes may be even more rapid than this, but in these initial experiments no samples earlier than 20 min were obtained. The secretory rate during the control period (before calcium or magnesium perfusion) appeared to be high, relative to that seen after hypocalcaemic stimulation. This may have been due to the administration of anaesthesia or to the fact that the inferior parathyroids were surgically removed. Still another possibility, suggested by the results obtained with

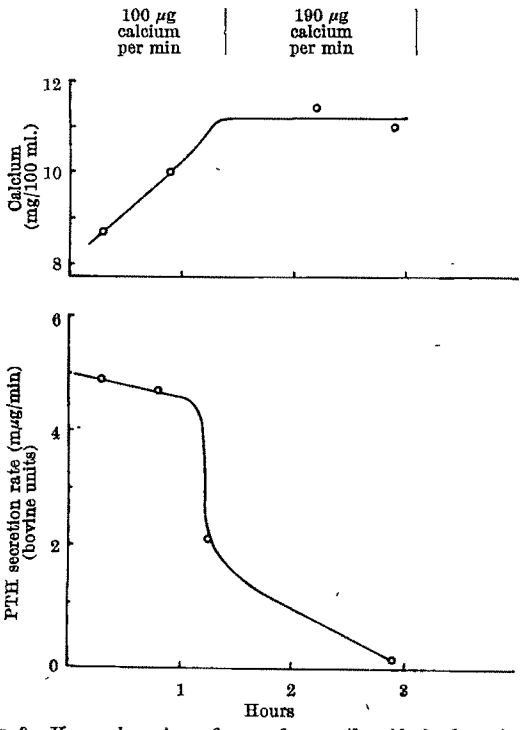

Fig. 9. Hypercalcaemic perfusion of a parathyroid gland *in situ* in a conscious sheep. This gland had been surgically isolated on the previous day, when the thyroid and inferior parathyroid glands were both removed. Blood flow was maintained at 2·2 ml./mn. The effect of hypercalcaemic perfusion on PTH secretion is shown

intravenous infusions in the cow[1], is that the initial perfusion with calcium or magnesium may have partially suppressed the response to subsequent EDTA stimulation.

Similar changes in PTH secretion rate were observed in a second anaesthetized goat (Fig. 8). In addition, perfusion of the gland in this animal with hypermagnesaemic blood caused a decrease in hormone secretion similar to that noted with hypercalcaemia. In a third experiment of the same type, an 80 per cent increase in plasma magnesium concentration resulted in a 30 per cent decrease in PTH secretion within 6 min.

In a conscious sheep, surgically prepared 24 h earlier, perfusion of a parathyroid gland with hypercalcaemic blood caused a similar decrease in the secretion rate of PTH (Fig. 9).

Direct evidence has already been presented[1] that the concentration of PTH in peripheral plasma responds in a reciprocal manner to alterations in plasma calcium concentration. Direct assessment of hormone secretion rate by determination of PTH concentration in the venous effluent of the isolated perfused parathyroid gland has fully confirmed these results. In addition, the perfusion studies indicate: (1) that the initial response of the gland to changes in calcium is rapid (less than 20 min); (2) that the receptor site for calcium regulation is in the parathyroid glands, as previously suggested[7-9]; (3) that the changes in plasma PTH concentration represent actual changes in secretion rate of hormone. Whether there are also variations in the distribution, excretion, or rate of destruction of the hormone in response to changes in concentration of calcium and other ions was not separately tested in these experiments.

There is an interesting similarity in the response to hypercalcaemic or hypermagnesaemic perfusion. Whether magnesium plays a significant part physiologically in regulating PTH secretion, as suggested by MacIntyre *et al.*[10], awaits additional investigation (the use of physiological changes in magnesium concentration by dietary or other means and evaluation of the effects of hypomagnesaemia).

The precise interrelationships of parathyroid and thyroid polypeptides in maintaining calcium homeostasis are now being investigated in a number of laboratories. Direct measurement of these hormones by radioimmunoassay, utilizing both isolated gland perfusates and peripheral plasma, should provide valuable information concerning their physiological function. Precise evaluation of the factors controlling hormone concentration, the rapidity and extent of changes in secretion rate, and alterations in the distribution, excretion or destruction of these proteins will allow more definitive assessment of the finely adjusted hormonal control of blood calcium concentration.

The major part of this work was completed while one of us (A. D. C.) was a visiting scientist in the U.S. National Health Institute, Bethesda, Maryland.

RELATIONSHIP BETWEEN ENVIRONMENTAL TEMPERATURE AND THE DEATH RATE OF WOMEN FROM NEOPLASMS OF THE BREAST

By DR. A. J. LEA
Statistics Unit, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2

IT has been shown for the countries of Norway, Sweden, Scotland, and England and Wales that the death rate from neoplasms of the breast in women is closely correlated with the mean annual temperature[1]. The investigation of this relationship has been extended to all countries for which comparable data were available, and the results are now reported.

The evidence on death rates was taken from a report by Segi and Kurihara[2]. Of the twenty-four countries with which these authors dealt, four were excluded for the following reasons: Canada, United States, and Australia, because the countries are so large that the idea of a mean annual temperature becomes absurd, and Israel because the bulk of the population has only been there for the

past 40–50 years. For the remaining twenty countries the death rates are expressed per 100,000 living and adjusted for age. For Belgium the rates are given only for the years 1954–61, for Portugal 1956–61, and for Chile 1950–57 and 1960–61. For the other countries the rates are for the years 1950–61. The mean values for these periods have been used.

Mean annual temperatures were calculated by a method of weighting. The populations of the largest towns, districts, counties and other divisions of the various countries are given in *Whitaker's Almanack* (1964) (ref. 3) and the *Statesman's Yearbook* (1964–65) (ref. 4). For most of these subdivisions one or more places are quoted by the Meteorological Office, and the mean annual temperature was obtained from published tables[5]. However, for many countries this left a large proportion of the population unaccounted for, and they were assumed to live at the mean temperature for the whole country. Then, by using the population living at each mean annual temperature as a weight, a weighted mean annual temperature for the country as a whole was obtained.

The mean annual temperatures were then plotted against the death rates from neoplasms of the breast, and it was at once obvious that the straight line relationship previously found for Norway, Sweden, Scotland, and England and Wales did not hold for the other countries, although a second degree curve gave a reasonable fit.

At this stage of the investigation it was thought that if the mean temperature influenced the death rate from breast neoplasms, then the range of temperature might also be a controlling factor. This seemed not unreasonable since Greenwood has shown[6] that of nineteen hens kept in a standardized environment (temperature 65° F, relative humidity 60 per cent, artificial light only) eighteen developed adenocarcinoma of the ovaries or oviducts, as compared with a complete absence of such tumours in a control series of fourteen hens kept under normal conditions for the same period.

The Meteorological Office includes in its published tables: (1) the monthly averages of the daily maximum and minimum temperatures; (2) the averages of the extreme values of the daily maximum and minimum for each month; (3) the absolute extremes which have occurred for each month during the entire period of recording. Of these three records (1) was chosen for the present purposes as it was considered to give a better reflexion of the temperature range than the others, because (2) is the average of the abnormal values and (3) is even more abnormal than (2).

The highest and lowest monthly averages were, therefore, taken as representing the range of temperature, and a 'range' for each country calculated by the method of weighted means as described for mean annual temperature. Various combinations of mean annual temperature and 'range' were plotted against the death rates, and it was found that the best fit was obtained by using mean annual temperature + 'range'.

Further evidence of the usefulness of this combination of mean annual temperature + 'range' in biological systems was received from Dr. P. S. Dixon of the University of Liverpool, where a similar result had been found experimentally for the effect of environment on the distribution of marine algae[7].

The technique of multiple regression was then applied to the data to obtain the best combination of mean annual temperature and 'range' for the observed death rates from breast neoplasms. It must, however, be kept in mind that the estimations of both death rates and temperature are known to be inaccurate and that it is not possible to estimate the degree of these inaccuracies. It follows that standard errors for the data derived from the foregoing calculation would have to be regarded with considerable suspicion, and it was finally decided that their use would tend to cause an impression of accuracy which could not be justified from the data.

It was found that:

$$y = 69{\cdot}5614 - 0{\cdot}5249R - 0{\cdot}6200M$$

where y is the expected death rate from neoplasms of the breast, R is the 'range' and M the mean annual temperature, from which it will be seen, bearing in mind the inaccuracies in the data, that 'range' and mean annual temperature produce approximately equal effects.

This provided an additional reason for using the combination of mean annual temperature + 'range', and it was decided to use this representation of the data for the continuation of the work, and to obtain data for all countries which presented them in such a way that they could be reduced to the Segi–Kurihara standard population[2].

Data for twelve more countries which fulfilled this condition were obtained from *Annual Epidemiological and Vital Statistics 1950 to 1961* (ref. 8). In addition it was found that the distribution of the female population of Iceland for the 1960 census did not differ significantly from the Segi–Kurihara standard, so that the crude death rate for that country could be used[9]. Finally the death rate for breast neoplasms for Singapore, adjusted to the Segi–Kurihara standard, is given by Muir[10]. Thirty-three countries were now available, and the data for them are shown in Table 1, with the 'best straight line' calculated from the data, and the resulting graph in Fig. 1. Calculation of the correlation between death rate and 'range' + mean annual temperature gave $r = -0{\cdot}7208$, $n = 31$, and P much less than 0·001.

Table 1. Death Rates from Breast Neoplasms (Age-adjusted), Mean Annual Temperature (MAT), 'Range' and Mean Annual Temperature + 'Range' for 33 Countries

	Country	Death rate	MAT	'Range'	MAT + 'range'
(1)	Ireland	25·7	49·0	30	79·5
(2)	Switzerland	21·5	44·0	46	90·0

(27)	Romania	7 5	46·5	59	105·5
(28)	Bulgaria	7 2	53·5	60	113 5
(29)	Iceland	26·0	41 0	29	70·0
(30)	South Africa (Whites)	21·7	63·0	42	105 0
(31)	Mexico	3·8	75·0	32	107·0
(32)	Venezuela	8·0	72·5	21	93·5
(33)	Columbia	5·6	70·0	18	88·0

The nature of the relationship between the environmental temperature and the death rate was found to be that the rate fell with increase of both mean annual temperature and 'range'. This, however, was complicated by an apparent repulsion between mean annual temperature and 'range'. Consideration of mean annual temperature and 'range' for all those places dealt with by the Meteorological Office, that is most of the inhabited world, showed that there was a very marked negative correlation

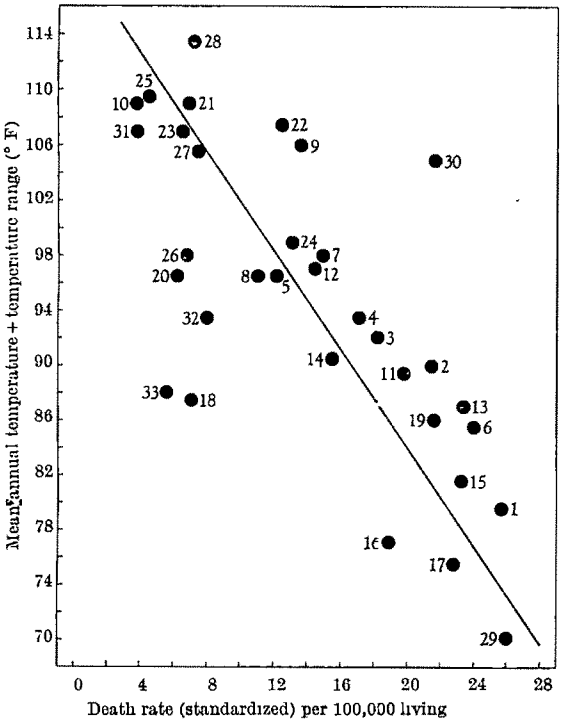

Fig. 1. See Table 1 for identification of numbers

between mean annual temperature and 'range', P again being much less than 0·001.

Mr. R. H. Clements of the Meteorological Office[11] has pointed out that this correlation is to be expected on an ideal world, because as one approaches the poles from the equator the mean temperature decreases but the conditions become more favourable for low temperatures in the winter half-year and for high ones in the summer half, hence the range increases. On the actual world the situation is, of course, more complicated by the atmospheric circulation, variations in cloudiness, and especially by the nature of the surface, land and sea. This explains some of the more remarkable results of Fig. 1, for example Iceland with mean annual temperature + 'range' of 70·0 and death rate of 26 as compared with Norway's mean annual temperature + 'range' of 93·5 and death rate of 17, the distance of the two countries from the equator being approximately the same.

It is now clear that the relationship previously found between mean annual temperature and the death rate from breast neoplasms for Norway, Sweden, Scotland, and England and Wales was a first approximation to a more complex relationship, and that the combination of mean annual temperature and 'range' provides a much wider relationship between environmental temperature and the death rate from these neoplasms. The same procedure carried out for other neoplasms produced no similar pattern, or in fact any pattern other than a random distribution. There are, of course, bad points on the graph, but in view of the uncertainties in the data this is to be expected. It may be of some importance that the countries which diverge most from the straight line are those which have been colonized from European countries, namely South Africa, Venezuela, Columbia and Chile.

Two factors which may influence the incidence of breast neoplasms have previously attracted attention, lactation and social conditions. The influence of lactation is based on experimental work in mice, but investigations of such a possibility in humans have failed because of the difficulties encountered in obtaining lactational histories in normal women[12]. While it is just conceivable that variations in breast-feeding in different countries might account for the observed differences in the death rate from breast neoplasms, the evidence which could prove or disprove this does not exist. Stocks[13] found an association between a social class index and the mortality index for breast cancer in women in thirty large towns in England and Wales for the years 1921–30, the correlation coefficient being $-0{\cdot}357 \pm 0{\cdot}159$. This is not significant at the 1 per cent level, and Stocks stated that there was apparently some factor other than economic and social differences operating to affect this cancer. As economic differences have been greatly reduced since 1921–30 it seems very improbable that such a factor could explain the variations in death rates shown in the present article.

The nature of this relationship remains completely obscure, but in view of the very high correlation there can be little doubt of its reality. Certain possibilities suggest themselves, but as they are at present without supporting evidence it is not proposed to discuss them at this stage.

I thank Sir Austin Bradford Hill, Mr. R. H. Clements, Prof. Hans Gruneberg, Dr. G. F. Marrian, Prof. C. A. B. Smith and Dr. C. C. Spicer for their advice and Dr. P. S. Dixon for permission to use unpublished material.

Correction added in proof. The death rate for Ireland (1) has been shown in Fig. 1 and Table 1 as 25·7. This is an error and should read 18·9 in both places.

CORTICAL LESIONS AND INTERHEMISPHERIC COMMUNICATION IN MONKEYS (*Macaca mulatta*)

By C. R. BUTLER

Medical Research Council Cerebral Functions Research Group, Department of Anatomy, University College, London, W.C.1

THE technique of restricting the visual connexions of each eye to the ipsilateral hemisphere of the brain by midline section of the crossed optic nerve fibres has permitted investigation of the function of the forebrain commissures in interhemispheric transfer of visual discrimination habits[1–3]. It has been reported[4] that if optic chiasma-sectioned monkeys are taught pattern discriminations with one eye open, the problems are correctly performed with only the other eye open, without further training. If, after thirty trials using this second eye, the forebrain commissures are cut (that is, the anterior commissure and the corpus callosum, plus un-

avoidably the psalterium situated beneath the callosum), it is found that the monkeys perform correctly with the first eye open, but imperfectly with the second eye. This suggests that communication between the hemispheres is incomplete or absent during the initial training. However, the amount of training necessary to bring the monkeys back to the correct performance with only the second eye open is significantly less than that given with the first eye open. It seems that communication occurs during the testing of the naïve side, before cutting the commissures, and the animal requires only a few more trials to complete the learning on that side. Further problems were then taught with only one eye open after the commissures had been cut, and these were not correctly performed with the second eye alone open until the monkey had received an amount of training comparable with that originally required[4]. Because of these and similar results in other species it is generally considered that the forebrain commissures mediate the communication of visual pattern training with one hemisphere to the other.

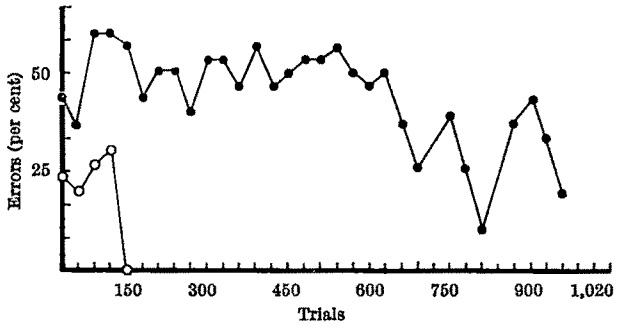

Fig. 1. Percentage of errors per 30 trial training session. Lesion, left inferotemporal; problem, 6- versus 5-point star. ●, Initial training on damaged side; ○, subsequent testing on intact side

Since the forebrain commissures concerned arise and terminate within the cerebral cortex, it was thought that suitable cortical lesions might disrupt interhemispheric communication. This has now been tested with three types of lesion. Various aspects of this work have been reported elsewhere[5–7]. The two optic chiasma-sectioned monkeys in Group I each sustained a large lesion of the frontal parietal and temporal cortex on one side, sparing the visual and motor areas. Before making the cortical lesion, these monkeys had been taught to discriminate + from ○ using the eye on the side later to be damaged, and a more difficult problem, ▲ from ■, using the other eye. After the cortical removals the first problem was solved correctly on the trained, damaged side only, even though the neocortical commissures had not been sectioned. The second discrimination was made correctly without further training with either eye open, although this second task was more difficult than the first, as judged by the number of trials needed in training. Thus the lesion interfered with communication from the damaged side to the undamaged side but not the reverse, producing an unexpected asymmetry in interhemispheric communication. This result would not have been possible if the communication between the two hemispheres had been completed during the initial training. A similar deficit in performance on 'difficult' discriminations, when using the eye projecting to the untrained side following cortical lesions on the trained side, has been found by Myers[8] in cats.

Post-operatively, these two monkeys were taught to discriminate Y from T using the eye on the damaged side, and ⊤ from ⊣ with the eye on the intact side. The first discrimination was performed correctly without further training using the eye on the untrained side, but the second discrimination was not. The lesion thus disrupted communication from the intact hemisphere to the damaged one. This asymmetry in the communication of post-operatively acquired learning is in the opposite direction to that found for pre-operatively acquired learning. These results were consistent in the two monkeys and present a challenge for interpretation. It was decided to repeat the experiments with more complete lesions confined to specific areas of cortex.

The three optic chiasma-sectioned monkeys of Group II sustained unilateral lesions in the inferotemporal area, which is concerned in the discrimination of visual patterns. Lesions in this area are known to produce specific visual deficits[9]. The pre-operative training was the same as for the previous group. Post-operative testing showed that communication was able to take place between the hemispheres in both directions. The asymmetry found in Group I was absent. The monkeys were then given 1,000 trials with the eye on the damaged side attempting to discriminate ⊛ from ⊛, but did not reach the criterion of three errors in each of two successive sessions of thirty trials, although the proportion of errors was slowly falling (Fig. 1). When the monkeys were tested on the same problem using the opposite eye, they reached criterion in about 150 trials. The score for other chiasma-sectioned monkeys with intact cortex trained monocularly on this problem is about 600 trials. Thus the inferotemporal lesion made learning on the damaged side slow and incomplete, yet the number of trials required on the intact side was only one quarter of that which would be expected if the latter had received no training. There is evidence[10–12] that in the situation described the remaining intact inferotemporal area is necessary for the slow learning of visual discriminations through the eye projecting to the damaged side. The results recorded here suggest, therefore, that communication from the damaged to the intact side during learning is enhanced by the participation of the intact inferotemporal area in the learning of visual discriminations.

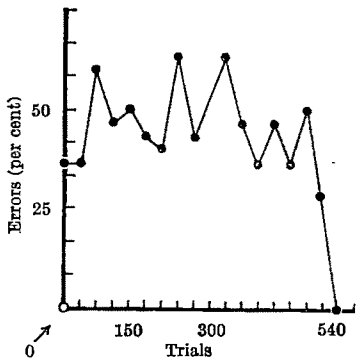

Fig. 2. Percentage of errors per 30 trial training session. Lesion, left inferotemporal; problem, ⊤ versus ⊣. ●, Initial training on intact side; ○, subsequent testing on damaged side

When the monkeys had reached criterion in discriminating the five- and six-point stars using the eye projecting to the intact hemisphere, they were re-tested with the other eye. They at once solved the problem correctly, in spite of the previous slow progress in 1,000 trials on this side. This result could mean that the solution to a problem is more easily communicated to the opposite hemisphere than is information about a discrimination problem that has not yet been solved completely. The result could, however, also be interpreted as an asymmetry such that communication from the intact hemisphere to the damaged hemisphere is more effective than in the opposite direction. To test that the communication from the intact side to the damaged side seen in the foregoing did not depend on the previous training given to the damaged side, a new problem, ⊤ versus ⊣, was trained

on the intact side. The animal performed correctly when the damaged side was tested (Fig. 2), showing perfect communication in this direction. A further control is now being undertaken using monkeys with inferotemporal lesions. This consists of varying the amount of training given to the damaged side on the six- versus five-point star problem to see if the amount of training necessary to complete the learning on the second, or intact, side varies correspondingly.

The experiments were repeated on the two chiasma-sectioned monkeys of Group III with unilateral lesions in the frontal granular cortex. The lesions were centred on the sulcus principalis and included the frontal eye fields (Fig. 3). Frontal lesions cause a variety of deficits and sometimes interfere with certain types of visual discriminations[14]. The pre-operative training was the same as in Group I and Group II. Post-operative testing revealed effective communication between the hemispheres in both directions, as in Group II. The post-operative training was the same as for Group II and again the six- and five-point star problem was unsolved after 1,000 trials with the eye on the damaged side open. When the other eye was tested, 600–800 trials were required to learn the problem, so there was no saving as in Group II. Moreover, subsequent re-testing with the eye projecting to the damaged hemisphere revealed a continued performance at chance level. The frontal lesion seemed, therefore, to have reduced communication between the two hemispheres in both directions (Fig. 4). This result was further tested by training a new problem, discriminating ∓ from ∔ using the eye on the normal side. This problem was solved correctly on the normal side, but subsequent testing through the eye on the damaged side again showed a performance at the level of chance. These results were consistent in the two monkeys used.

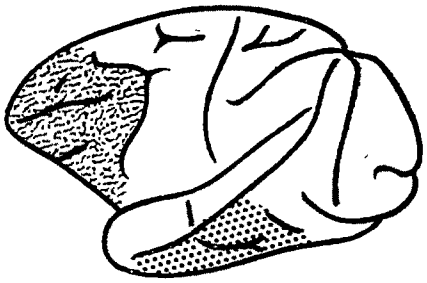

Fig. 3. Diagram to show extent of cortical lesions sustained by animals in Group II and Group III. Regular stippling (below), inferior temporal lesion (Group II); irregular stippling (above), frontal lesion (Group III)

These experiments on the effect of cortical lesions on interhemispheric communication have produced a number of unexpected results, and have suggested several further experiments. In the first place, properly designed experiments are needed to make certain that interhemispheric communication normally takes place during the testing of the naïve hemisphere rather than during the initial training. Secondly, the asymmetry found in the first group of monkeys in the communication of pre-operatively learned problems needs to be confirmed in a larger group, for it was not seen after frontal, or inferotemporal lesions, and is at present difficult to explain. It implies that the lesion disrupts communication from the damaged to the intact side without affecting retention on the trained, damaged side.

The most surprising finding was that interhemispheric communication can be enhanced as well as obstructed by appropriate cortical lesions. The explanation suggested for the asymmetry in the second group of monkeys was that communication from the damaged to the intact side during learning is enhanced by the necessity for the intact inferotemporal area to participate in the learning of visual discriminations seen through the eye on the damaged side. This explanation might also apply to the similar asymmetry in the communication of post-operative learning in the first group of monkeys, except that the lesion in these monkeys involved only a small part of the posterior inferotemporal area. The prestriate cortex was, however, involved in the lesion and this would have reduced the visual input to the inferotemporal area. The frontal lobe was also extensively damaged in these first two monkeys; but the results are not similar to those for the third group of monkeys with pure frontal lesions.

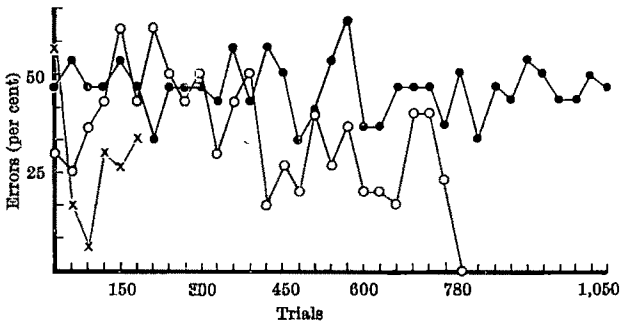

Fig. 4. Percentage of errors per 30 trial training session. Lesion, left frontal; problem, 6- versus 5-point star. ●, Initial training on damaged side; ○, subsequent testing on intact side; ×, subsequent re-testing on damaged side

The inability of the third group of monkeys which had frontal lesions to learn the visual discrimination given on the damaged side was unexpected, though similar cases of increased difficulty in learning have appeared in the literature[10,13]. The frontal lesions prevented the correct performance of a visual discrimination using the eye projecting to the damaged side even after it had been trained to criterion on the intact side. Whether this is due to some quite different disability in the testing situation such as increased distractability, visual neglect or lack of drive inhibition as described by Brutkowski *et al.*[14] is at present unknown. Further results suggest that the animals with frontal lesions respond more quickly to the discrimination stimuli when using the eye projecting to the damaged side than when using that on the normal side. Possibly the response time is insufficient to allow adequate examination of the stimuli. Comparison with the deficit in the second group of monkeys and the explanation offered for it suggests that the deficit produced in the monkeys with frontal lesions cannot be compensated by the activity of a similar intact structure on the other side, so that interhemispheric communication is not promoted. These results suggest that the examination of the effect of cortical lesions on interhemispheric communication is a useful method of exploring aspects of the functioning of cerebral cortical areas, and a fertile source of further problems.

I thank Prof. J. Z. Young, Dr. J. L. de C. Downer and Dr. B. G. Cragg for their advice.

ASTRONOMY

Jupiter's Great Red Spot

The great red spot of Jupiter has puzzled astronomers since its discovery in 1857 (or since 1664 if it is identical with the feature seen by Robert Hooke). It is generally conceded to-day that Jupiter is approximately 80 per cent hydrogen by weight[1-3], and the best modern evidence does not conflict with the assumption that hydrogen predominates in the atmosphere of Jupiter to the same extent as in the planet's bulk[4]. It has proved difficult to conceive of an 'object' able to 'float' in a surfaceless ocean[5] of supercritical hydrogen gas. Therefore the suggestion of Hide[6] that the red spot might not be a flotation phenomenon at all but rather a 'Taylor column' was an intriguing alternative. Unfortunately, it has not been possible as yet to prove hydrodynamically that a Taylor column can be realized in Jupiter's atmosphere; for one does not know enough about the hydrodynamic conditions of the atmosphere (we shall return to this point later). Moreover, certain observed phenomena appear to indicate that the rather restrictive requirements for the existence of a Taylor column are not met by the red spot. Without here going into these arguments, we merely wish to propose a novel and alternative explanation based on a theoretical prediction of J. D. van der Waals[7] which has been verified in some detail by Krichevsky and Zichs[8], Kennedy and Takenouchi[9] and others.

Multi-component fluids with one polar component can show phase separation over a broad range of temperatures. As a rule the temperature range of immiscibility of fluid phases begins somewhere between the highest and lowest critical temperatures of the pure components and extends indefinitely upward, in so far as is known. In two-component two-phase systems the phases generally differ in density, but continuous changes in pressure and temperature can reverse the sign of the difference in density of the two phases. Moreover, there is a finite (univariate) range of conditions for which the two distinct phases have equal densities[9]. The two-component system is univariate in the sense that one of the two degrees of freedom allowed by the phase rule is lost owing to the stipulated equality of densities. However, three-component systems (for example, hydrogen, helium and ammonia) could show decomposition into two phases having equal densities over a finite area of the p,T plane.

Since the atmosphere of Jupiter is predominantly composed of the non-polar gas hydrogen, though the polar gas ammonia is known to be present, we feel that possibly the red spot is merely a region where phase separation occurs under the condition that the two distinct phases have the same density, but different compositions. Hence the 'red spot phase' would be buoyantly neutral with respect to its surroundings—a thermodynamic Cartesian diver.

We anticipate objections to this view, which we shall not attempt to meet here. Experiments we hope to see forthcoming in the near future may very well prove that a multi-component gas matching Jovian surface conditions does not show the behaviour of the systems already investigated[8,9]. In that case the objections would stand with no rebuttal possible. On the other hand, if phase separation does occur in such gases, it is clear that the hydrodynamic theory of the Jovian atmosphere may be significantly—if not profoundly—affected. We shall then present a more detailed set of reasons for our belief that the red spot may be, after all, merely a normal manifestation of the thermodynamics of multi-component fluids.

We would like to underscore the fact that our remark concerning the possible effects of the separation of fluid phases on the hydrodynamics of the Jovian atmosphere would deserve attention even if Jupiter had no red spot. As a concrete illustration of how the phase separation phenomena in supercritical gas mixtures might alter hydrodynamic flows one can imagine a cylinder in the laboratory filled with pure water vapour maintained at 260° C and the pressure raised from 1,500 to 2,500 bars and thereafter reduced to 1,500 bars. Naturally, owing to the small displacements, the hydrodynamic mass velocities are small and at most of the order of the piston velocities, except near the region where the moving piston meets the cylinder walls so that the usual local lubrication flows would arise. However, if the cylinder is filled with a mixture of carbon dioxide (say, 30 per cent by mole) and water and the same process repeated, a glance at Fig. 8 in ref. 9 shows that the same isothermal cycle in pressure would cause dramatic effects. For at 1,500 bars the bottom of the cylinder would contain a phase with 17·5 per cent mole per cent of carbon dioxide, while a lighter phase with 50 per cent carbon dioxide would fill the top. On compression to 2,200 bars the carbon dioxide content of the bottom phase would rise to about 21 per cent and that of the phase on top would be depleted to approximately 47 per cent. Further compression would again lower the mole per cent of carbon dioxide in the phase which originally was at the bottom; but then the bottom phase becomes less dense, and in general, if the cycle is not too rapid, the two phases must reverse positions in the cylinder every time the pressure crosses 2,200 bars, approximately. Consequently, in this very simple system the hydrodynamic regime is altered drastically by the phenomenon of phase separation.

ASTROPHYSICS

X-ray Emission from Very Dense Stars

In recent years few localized astronomical X-ray sources have been discovered by rocket- and balloon-borne instruments. To explain the X-ray emission by celestial bodies several production mechanisms have been invoked such as the inverse Compton effect, bremsstrahlung in a 'hot' plasma cloud, synchrotron radiation and thermal emission.

These attempts have been reviewed by Giacconi and Gursky[1], by Manley[2] and by Burbidge *et al.*[3].

The purpose of this communication is to consider yet another mechanism, which accounts in a satisfactory manner for the emission of X-rays from punctual sources. It fails, however, to account for the emission from extended sources.

Consider a very dense neutron star such as was described by Hoyle, Narlikar and Wheeler[4]. They showed that for a star possessing rotation, the usual treatment of the maximum mass does not apply. One can obtain a disk-like structure, of radius a, thickness b, rotating around an axis perpendicular to the disk in its centre, where the mass M may be made as large as one may desire.

They pointed out that since a neutron star is thought to be formed catastrophically, it will arrive at its stable configuration through large dynamical oscillations, thus dissipating a total energy of 10^{54} ergs for a star of mass $M = 5\,M_{\odot}$.

Such a star, the density of which is of the order of 10^{15} g cm^{-3} and the dimensions of which are of the order of a few kilometres, will develop a polar magnetic field H of the order of 10^{10} gauss.

Dynamical oscillations of the main body of a neutron star imply oscillations of the associated magnetic field. As the density ρ falls steeply at the surface, the hydromagnetic wave speed $v = H/\sqrt{4\pi\rho}$ becomes of the order of the velocity of light and the oscillations become electromagnetic rather than hydromagnetic. Outside the immediate surface of the star, electromagnetic waves of wave-length λ are generated, with $\lambda/2\pi$ of the order of the linear dimensions of the star.

The polar magnetic field H can be expressed in the form: $H = H_0 + \delta H \cos \omega t$, where $H = 10^{10}$ gauss is the stationary field and $\delta H \cos \omega t$ is the variable part of the field due to electromagnetic oscillations, with $\omega = v/a$.

If one relates the magnetic field of the star to its angular momentum, it would seem reasonable to admit that during the dynamic oscillations of such a disk-shaped star the relative variation of angular momentum, and thus the relative variation of the magnetic field, is of the order of $\delta H/H \cong 10^{-4}$.

Although neutrons are dominant in the star, electrons and protons are also present. The electromagnetic waves of frequency ω will exert radiation pressure, particularly near the rim of the star, and will accelerate electrons to an average energy of 10^9 eV. These electrons will be trapped in the magnetic field of the star, and will spiral tightly around the magnetic lines of force emitting synchrotron radiation.

The tightly spiralling electrons will create a toroidal magnetic field H_t of the same order of magnitude as the polar field H.

Let n be the average density of electrons creating the toroidal field, then:

$$H_t = H = \frac{4\pi I}{l} = \frac{4\pi e c n \pi a b}{2\pi a}$$

where e is the charge of the electron and c the velocity of light (the electrons being relativistic). If a is taken to be 3×10^6 cm, and $b = a/10$, one has $n = 1{\cdot}1 \times 10^{13}$ electrons cm^{-3}.

The radiation pressure at the rim of the disk is:

$$\frac{(\delta H)^2}{12\pi} \cong 2{\cdot}6 \times 10^{10} \text{ ergs cm}^{-3}$$

Each electron thus gains an average energy of:

$$E = \frac{2{\cdot}6 \times 10^{10}}{1{\cdot}1 \times 10^{13}} \cong 2{\cdot}4 \times 10^{-2} \text{ erg}$$

say 10^9 eV.

Electrons with an average energy of 10^9 eV spiralling in a magnetic field of $H = 10^{10}$ gauss emit synchrotron radiation with a spectrum in which the peak flux has a characteristic frequency:

$$\nu_c = 1{\cdot}26 \times 10^6 H \left(\frac{E}{mc^2}\right)^2 \cong 5 \times 10^{22} \text{ c/s} \cong 2 \times 10^8 \text{ eV}$$

that is γ-rays of 200 MeV.

The total power radiated by an electron is:

$$p = 10^{-3} H^2 \left(\frac{E}{mc^2}\right)^2 \text{ eV.sec}^{-1} =$$

$$1{\cdot}6 \times 10^{-15} H^2 \left(\frac{E}{mc^2}\right)^2 \text{ergs.sec}^{-1} = 0{\cdot}6 \times 10^{12} \text{ ergs.sec}^{-1}$$

The star will radiate a total power of:

$$P = 2\pi a b^2 n p \cong 10^{43} \text{ ergs.sec}^{-1}$$

The dynamical energy of oscillations of 10^{54} ergs will be dissipated in 10^{11} sec ($\cong$ 3,000 years). However, if one considers the gravitational redshift, which is quite high, that is:

$$\frac{\Delta\nu}{\nu} = -\frac{GM}{c^2 a} = -0{\cdot}25$$

the whole spectrum should be shifted towards the lower frequencies and the time of dissipation of the dynamical energy will be somewhat longer.

The frequency analysis of the synchrotron radiation could be obtained if the energy spectrum of electrons were known. To simplify matters it will be assumed hereafter that the spectrum of synchrotron radiation is of the form A/ν (ref. 5). The total power emitted is then:

$$P = \int_{\nu_1}^{\nu_2} A \frac{d\nu}{\nu} = A \log \frac{\nu_2}{\nu_1}$$

The lower limit of integration, ν_1, occurs quite naturally at the frequency at which the dielectric constant:

$$1 - \frac{n e^2}{\pi m \nu^2}$$

of the electron cloud becomes zero. Thus:

$$\nu_1^2 = \frac{ne^2}{\pi m} = 9 \times 10^{20} \text{ and } \nu_1 = 3 \times 10^{10} \text{ c/s}$$

For the higher limit of integration, ν_2, one may take $2\,\nu_c$—ν_c being the characteristic frequency. This is justified by the fact that for frequencies higher than ν_c the energy in the synchrotron pulse falls off exponentially It can be remarked here that the value of A is very insensitive to the limits of integration. One finally has:

$$A = P/\log \nu_c/\nu_1 \cong 3{\cdot}5 \times 10^{41} \text{ ergs.sec}^{-1}$$

The number of X or γ photons emitted per sec by the star in the bandwidth $\Delta\nu$ is then:

$$\Delta N = \frac{A\Delta\nu}{h\nu^2}$$

photons sec^{-1} (h is Planck's constant). Consider a star the distance of which from the Earth is R, then the number of photons, X or γ, received at the surface of the Earth (neglecting absorption) per unit area during one second in a band-width $\Delta\nu$ is:

$$\Delta n = \frac{A\Delta\nu}{4\pi R^2 h\nu^2}$$

As an example, consider a star for which $R = 5 \times 10^{22}$ cm and compute Δn for X-rays of 5 KeV, that is $\nu = 1{\cdot}2 \times 10^{18}$ sec^{-1}. Assuming $\frac{\Delta\nu}{\nu} = 0{\cdot}25$, one has $\Delta n_x \cong 3{\cdot}5 10^2 X \text{ cm}^{-2}$ sec^{-1}. The number of γ-photons of 200 MeV received under the same conditions will be $\Delta n_\gamma \cong 10^{-2}\,\gamma$ cm^{-2} sec^{-1}. These numbers are somewhat higher than those obtained experimentally[6,7]. If, however, one considers the gravitational redshift the discrepancy between calculated and observed numbers decreases. The corresponding number of optical photons, calculated under the same general conditions, is:

$$\Delta n_{ph} \cong 10^6 \text{ ph.cm}^{-2} \text{ sec}^{-1}$$

Whereas the absorption by interstellar matter is quite small for X-rays and γ-rays, it is by no means negligible

for optical photons. In fact, if account is taken of absorption by interstellar matter, the star is scarcely detectable in the optical band.

It is interesting to compute the unattenuated power which one could expect to receive on the surface of the Earth in the radiofrequency band, above the cut-off frequency ν_1. For $\nu = 10^{10}$ sec^{-1}, one has $\Delta p = 10^{-18}$ W m^{-2} (c/s)$^{-1}$. This is a very high figure indeed. However, these waves would be strongly attenuated in regions of the electron cloud, where the densities are higher than the average calculated. In spite of this fact it would be interesting to observe X-ray emitters in the centimetre band of radio frequencies.

SPACE SCIENCE

An Effect of Nuclear-reactor Operation in Space

There is considerable development effort towards producing nuclear reactors for SNAP (systems for nuclear auxiliary power) applications. Obviously the performance of these reactors in the space environment is a matter of some concern.

Both the effect of the reactor system on the space environment and the effect of the space environment on the reactor system should be carefully considered. Recently it was pointed out that a nuclear reactor could have a definite effect on its environment while orbiting in the geomagnetosphere[1]; now it appears that the environment can have a very definite (and unexpected) effect on the reactor system.

In particular, the photonic flux from a nuclear reactor will produce Compton electrons in nearby material. Under planetary conditions, these electrons would dissipate their energy through atomic interactions, and then return to the immediate vicinity of their origin because of electrostatic attraction. In space, however, energy dissipation is small enough to be neglected, and magnetic fields will at best cause only a small percentage of the ejected electrons to follow paths returning them to the reactor system, so electrostatic forces must play an especially large part in establishing a steady state condition. This suggests that the reactor system might achieve a noticeable positive potential while in operation. The magnitude of this effect can be determined from a few rough approximations.

Let us assume that a 1 MW (thermal) nuclear reactor is in polar orbit at an altitude of 1,000 km above the surface of the Earth. Let us further assume that the heat rejection radiator is placed about the reactor as a spherical surface. Since the radiator area would be about 120 m^2 (ref. 2), this yields a thin spherical shell (perhaps 2 cm thick) of 3·1 m radius. At the centre of the shell would be located the reactor and reflector. The reactor should be no more than 30 cm in radius (assumed spherical here), and the reflector would perhaps be 4 cm of beryllium.

It is reasonable also to assume that the average power density of the reactor is less than twice that of the power density at the reactor's edge. This provides a power density near the reactor's edge of $4{\cdot}4 \times 10^{-6}$ MW/cm^3, which in turn yields a fission density of $1{\cdot}36 \times 10^{11}$ fissions/cm^3-sec. Each fission can be considered to yield 7 photons at 1 MeV per photon[3].

Now 1 MeV photons have an e-folding path length in plutonium fuel of 0·7 cm, so the photon production region can be taken as $7{\cdot}9 \times 10^3$ cm^3. This yields a thin shell source of $7{\cdot}5 \times 10^{15}$ photons/sec (of 1 MeV each). However, geometric considerations should lower that figure to about $3{\cdot}5 \times 10^{15}$ photons/sec.

The 4 cm of beryllium should attenuate the photons to approximately 2×10^{15} photons/sec. So, 2×10^{15} photons/sec (of 1 MeV each) should strike the inner wall of the radiator. If we assume the radiator to be 2 cm (of aluminium) thick, the photons/sec through the outer surface should approximate $1{\cdot}4 \times 10^{15}$ photons/sec. When only those electrons within an electrons e-folding distance of the radiator's outer surface are considered, 3×10^{13} electrons/sec are Compton scattered.

If we consider further the angular spread of Compton scatter, about 5×10^{12} electrons/sec of 0·8 MeV maximum energy can be considered as ejected from the reactor system. If no other factors were considered, the reactor system would rapidly approach a positive potential of 0·8 MV. However, there are other factors which should be included.

Over the reactor's orbit, there are flux levels of trapped electrons and positive ions as low as 10^3 particles/cm^2 sec and lower[4]. The positive ions would tend to be repelled from a positively charged reactor system, while the electrons would just as effectively be attracted to the system. The large surface area of the reactor system would tend to acquire about 1×10^9 electrons/sec. This, of course, assumes the very doubtful complete repulsion of all positive ions.

We now have a Compton electron current away from the reactor system, and a trapped radiation electron current into the system. When the energy distribution of the Compton electrons is considered in light of the electrostatic build-up, a steady state potential of about 0·79 MV is found to exist on the reactor system.

The importance of this potential can be better evaluated by noting that the reactor system described would have a capacitance of $3{\cdot}4 \times 10^{-10}$ farads. So the electrostatic energy stored would be 100 joules.

The discharge of 100 joules might puncture a very thin surface; but it would appear that this effect would provide merely a nuisance for the case investigated. The positive charge would tend to make objects in contact with the reactor system surface be repelled from that surface, and from each other.

However, it would seem advisable to determine the magnitude of this effect to be expected for the particular space mission planned for each nuclear reactor.

PHYSICS

Attenuation of Shock Waves by Cooling

The attenuation of shock waves was the subject of a recent investigation[1], where energy loss through heat transfer was suggested as the mechanism.

Experiments conducted by me[2] have illustrated that heat loss from shock waves can be an effective method of attenuation. Here, liquid nitrogen was injected into shock waves.

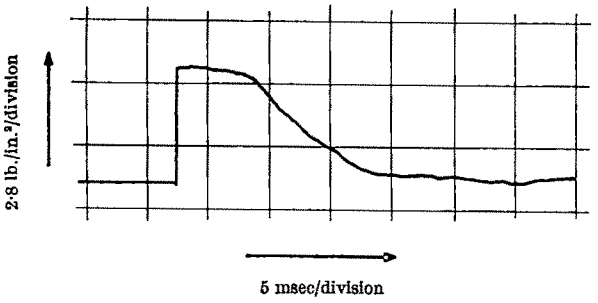

Fig. 1. Pressure-time record of undisturbed shock wave

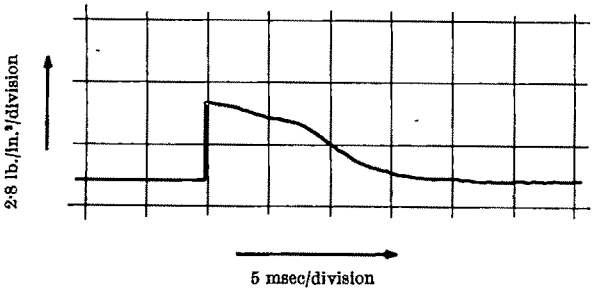

Fig. 2. Pressure-time record of similar shock wave following injection of liquid nitrogen

Fig. 1 illustrates a pressure-time record of a shock wave in a 2 × 1·5 in. shock tube. Fig. 2 illustrates the pressure-time characteristics of a similar shock wave, following the injection into the wave of 3·8 c.c. of liquid nitrogen.

The total impulse in the shock wave was reduced from 46 lb/in². msec to 31 lb/in². msec.

Although the quantities of liquid nitrogen required limit the usefulness of this technique on any large scale, its use on a small scale would appear to present many intriguing possibilities.

Lifetimes of Saturable Absorbers

The use of saturable absorbers such as aluminium phthalocyanine for the passive Q-switching of ruby lasers[1] raises the question of the lifetime of the active molecule. We have measured the lifetime of that state of aluminium phthalocyanine which corresponds to absorption at or near 6943 Å. Similar data for magnesium phthalocyanine have been obtained, for comparison with literature values.

In their theoretical treatment of passive Q-switching, Szabo and Stein[2] point out that this may need modification for the case of short lifetimes, and the reservations of Armstrong[3] concerning the effect of short spontaneous lifetime on the application of Franz and Nodvik's[4] saturable amplifier theory to saturable attenuators also showed the need for lifetime measurements to be made *in situ* or in high-flux environments similar to the laser resonator. Using the low-flux phase-shift fluorometer method, Dmitrievskii *et al.*[5] have found that the excited-state lifetimes of magnesium and zinc phthalocyanines in various solvents lie in the ranges 6·5–8·6 nsec and 3·0–4·6 nsec respectively. Gires and Combaud[6] have established that the excited-state lifetime of chloro-aluminium phthalocyanine in chloronaphthalene is less than 10 nsec.

We have photographed directly the time variation of the fluorescence of a solution of chloro-aluminium phthalocyanine in chloronaphthalene when excited by a giant pulse from a Q-switched ruby laser. Comparison with a simultaneous photograph of the exciting light yielded the lifetime.

The output from a 2 in. × 0·25 in. ruby laser, with external reflectors and a Pockels cell Q-switch, was focused into a 6 × 10^{-4} M solution of chloro-aluminium phthalocyanine to give a line source of fluorescence about 0·3 mm wide. This was focused on the photocathode of an S.T.L. image converter camera, operating in the streak mode, the line of fluorescence thus constituting the effective slit of the streak recording system. A small fraction of the laser beam was deflected on to an opal glass screen giving a spot of 0·2 mm diameter which was also in the field of view of the camera. Records were made on Kodak 'Royal-X Pan' film which was carefully calibrated for density versus relative incident light intensity. As there is no reciprocity failure for exposure times shorter than 1 msec (ref. 7) this film calibration was performed with a xenon flash lamp and standard step wedge.

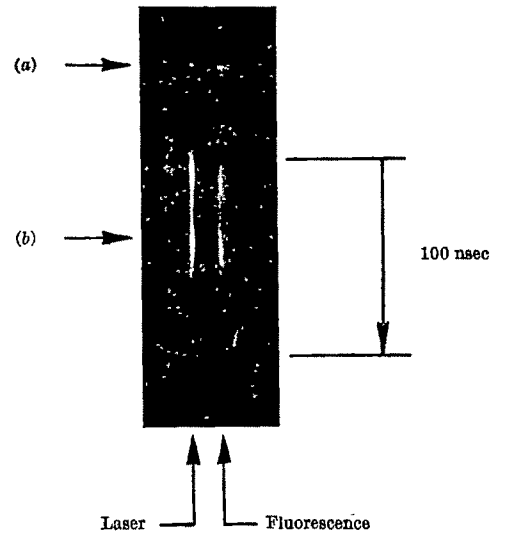

Fig. 1. (*a*) Stationary image; (*b*) streak record, time increasing downwards

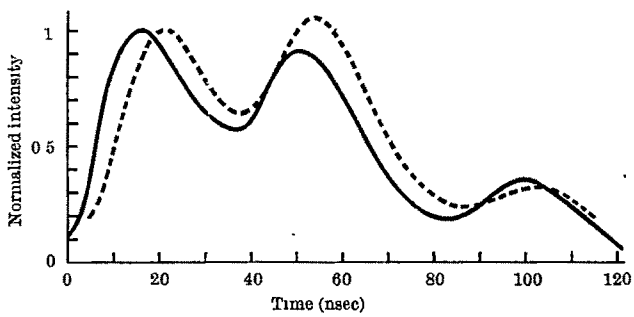

Fig. 2. —, Laser intensity; - - -, fluorescent intensity (normalized to unity near 20 msec)

The experimental records are shown in Fig. 1. The stationary patterns *a* show the effective slit during the course of the experiment. In the streak mode *b* the time-variation of the laser and fluorescent intensities are shown and the delay in fluorescent output due to the lifetime of the absorber may be seen by eye. Scattering at 6943 Å was found independently to be less than 4 per cent. The streak records were scanned along the time axis with a microdensitometer, and the wave-forms (Fig. 2) obtained after applying the film calibration. These show the gross effect of a time delay of about 5 nsec, but a more careful analysis was thought warranted.

Assuming that the excitation process is a simple two-level transition with a single decay process, and that

the number of molecules, n, in the upper state is small compared with the number in the ground state, then:

$$\dot{n} = PI - n/\tau$$

where I is the normalized incident intensity, PI is the rate of induced absorption, and τ is the lifetime of the excited state. The fluorescent intensity I_F is proportional to n and hence, by integrating over times t_1 to t_2, we obtain:

$$\frac{I_F(t_2) - I_F(t_1)}{\int_{t_1}^{t_2} I\,dt} = Q - \frac{1}{\tau}\frac{\int_{t_1}^{t_2} I_F\,dt}{\int_{t_1}^{t_2} I\,dt}$$

where Q is a constant.

The integrals of this equation were evaluated for intervals $(t_2 - t_1) = 10$ nsec over the wave-forms of Fig. 2 and the left-hand side plotted against the multiplier of $1/\tau$. A least squares fit of a straight line to these points gave a value of 5·3 nsec for τ (estimated standard deviation, 1 nsec). A second set of results gave 4·4 nsec.

To examine the validity of the method, an observation of the lifetime of magnesium phthalocyanine in chloronaphthalene was made and gave 9 nsec, which is in substantial agreement with the results of Dmitrievskii *et al.*[5], who used different solvents.

A lifetime of 5 nsec is not large compared with the usual photon lifetime in a laser resonator and this could limit the application of the simple theory of the passive Q-switch laser. A quantitative analysis of the possible effects of this parameter is at present being carried our in these laboratories.

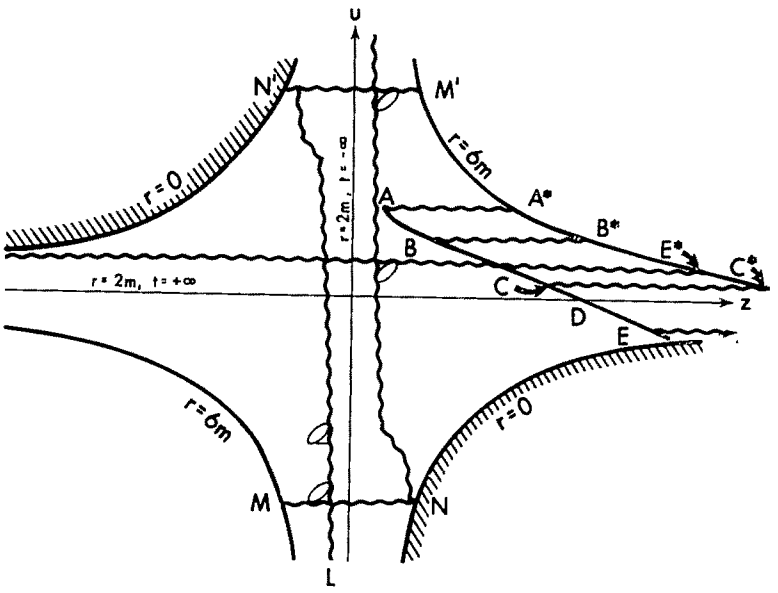

Fig. 1 The uz plane, showing null (wavy) lines and future null cones in the domain $(r > 2m)$ where they can be defined. Accepting a Euclidean topology for space-time, it is natural to interpret the figure as a map of the union of the 2-spaces $\theta = c_1$, $\varphi = c_2$, and $\theta = \pi - c_1$, $\varphi = \pi + c_2$. Thus, M, M' are events occurring at diametrically opposite points of a 3-space $t = \text{const.}$, and N, N' are to be identified. The light wave $LN'M'$ sent radially inwards by a stationary observer at $r \gg 2m$ reaches the diametrically opposite observer after a co-ordinate time-lapse $\Delta t \approx 2r$. Radial light-signals emitted by a freely falling clock at successive moments A, B, C, D, E are received by an external stationary observer at A^*, B^*, C^*, never, and E^*. Light signals emitted along section DE are received in inverted order, and may be said to be red-shifted into negative frequencies

Radial Motion in the Schwarzschild Field and the Issue of Gravitational Collapse

According to present relativistic ideas, a test particle released from rest at a distance r_{max} from a central point mass m appears (from the point of view of an external observer) to slow down as it falls toward the Schwarzschild radius $2m$, reaching it only asymptotically. This is in contrast with the Newtonian picture of a rectilinear oscillation with half-period $\pi(r^3_{max}/2m)^{1/2}$.

In fact, the proper time required to reach $r = 2m$ is finite, and the particle's career can be explored beyond this. But it is thought that, having once disappeared behind the observer's event horizon, the particle remains permanently sealed off from optical observation. It is concluded that the Schwarzschild sphere acts as a 'unidirectional membrane'[1] for particles and light-pulses dropped in from outside. Since both the field equations and the static boundary conditions are reversible, this conclusion (while not logically impossible) is difficult to understand.

Exactly the same considerations apply to the homologous gravitational collapse of a pressure-free sphere of mass m, since particles on the surface are effectively test particles in the exterior Schwarzschild manifold $V(m)$. One encounters the same disparity between the Newtonian picture of a reversible pulsation and the strange but generally accepted[2] contemporary description[3] of asymptotic shrinkage to $r = 2m$ and isolation from the external observer.

The current relativistic conception rests on the implicit assumption (for which no justification is apparent)* that events occurring 'later' in the history of a test particle in $V(m)$ also occur later in the history of an external observer. I shall present arguments to support the contention that this assumption and the conclusions derived from it are fallacious.

The line-element:

$$ds^2 = 2du\,dz + (z^2/2mr)\,du^2 + r^2\,(d\theta^2 + \sin^2\theta\,d\varphi^2)$$
$$r = 2m + uz/4m$$

is regular for $r > 0$ and convertible to the standard Schwarzschild form by the substitution:

$$t = r - 2m\ln(u/2z)$$

in the domain $(uz > 0)$ where the co-ordinate t is defined. It therefore represents an analytic extension of the Schwarzschild manifold, and it may be shown to be geodesically complete.

For a test particle started from rest at $r = r_{max} = 2m\csc^2\alpha$, the (analytically extended) parametric equations of the path are:

$$r(\Theta) = 2m\sin^2\Theta\csc^2\alpha$$
$$u(\Theta) = 4m\csc\alpha\sin(\Theta + \alpha)\exp G$$
$$z(\Theta) = 2m\csc\alpha\sin(\Theta - \alpha)\exp(-G)$$

where:

$$4\sin^2\alpha\,G = 1 + \csc\alpha\sin(2\Theta - \alpha) - 2\cot\alpha\,(1 + 2\sin^2\alpha)\Theta$$

* An appeal to extraneous considerations of causality does not justify recoiling from a consistent follow-through of the motion according to the principles of general relativity. Relativity is not automatically consistent with intuitive preconceptions of causality. The new description presented here indeed appears to violate causality, though only within a radius comparable with the Schwarzschild radius.

When $r_{max} = 2m$ this time-like geodesic is a closed loop (Fig. 2). This means that the accustomed global assignment of a time-arrow breaks down inside the Schwarzschild sphere. That is, each individual observer traverses his world-line in a definite sense, so that the relation 'earlier-later' retains a meaning for him (except at isolated points); however, it is impossible, in the domain $r < 2m$, to distinguish 'past' and 'future' halves of the null cone in a globally consistent way[4].

In general, the motion is oscillatory, the co-ordinate time between successive maxima being:

$$\Delta t = 2\pi m \csc^3\alpha \cos\alpha (1 + 2\sin^2\alpha)$$

For $r_{max} \gg 2m$ this formally agrees with the Newtonian result.

A remarkable feature of the motion is the existence of events such as X (Fig. 2) at which the world-line intersects itself. For large r_{max}, the radial co-ordinate at this event has the value:

$$r(X) \approx 2m + 4m \exp(-\pi/2\alpha^3) \quad (\alpha \to +0)$$

The well-known paradoxes[4] associated with self-collision are invalidated if one assumes that exposure to conditions at the singularity $r = 0$ erases every type of organized structure, in particular (human or mechanical) 'memory'.

A detailed description of the homologous collapse of a ball of dust would be complicated. However, the preceding equations apply to the geodesics followed by particles at the surface, and therefore give a correct account of the superficial aspects of the motion. The history of the surface is thus depicted by an external observer as a V-shaped curve of the form $BXF \ldots$ (Fig. 2). This means the ball is observed to be pulsating elastically, with maximal radius r_{max} and a minimal radius between 2 m and 2·5568 m.

For a sphere of 10^8 solar masses collapsing from the Chandrasekhar radius of instability[5], the period of pulsation is about 20 years. In practice, the pulsations will be slowed by anisotropies and viscous effects, and quickened by loss of amplitude due to radiation, neutrino emission and ejection of matter streams with escape velocities (mainly at the minimal radius). It seems that this picture offers hope of understanding the extended lifetimes, light variation and coherence of flashes which have been such puzzling features of the quasars.

The final stage in the evolution of such an object supervenes when the amplitude of the pulsation has died down to the Schwarzschild radius. The interior is in a state, characterized by multiple self-collisions, which can properly be termed primordial chaos. It is interesting to speculate that in this condition the body is thermally dead. All irreversible processes must have ceased, since there is no preferred time-direction in which they could operate.

Fuller accounts of this work will appear shortly in *The Physical Review* and *Il Nuovo Cimento*.

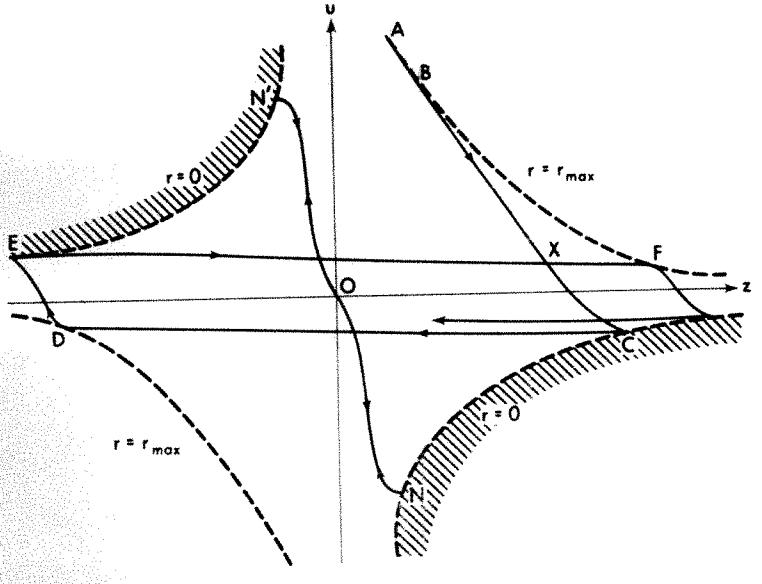

Fig. 2. Impressions (not to scale) of the time-like geodesic paths of a test particle with $r_{max} = 2m$ (the loop $ON'ON \ldots$) and a particle with $r_{max} > 2m$ (the curve $BCDE \ldots$). The curve $ABCDE \ldots$ may also be regarded qualitatively as the history of a massive thin spherical shell which has been held at rest (section AB), then released and allowed to fall under its own weight, as seen in the exterior Schwarzschild space. In this case, diametrically opposite points of the figure should be identified, and the first self-collision is not at X, but a point X^* in the first or third quadrant obtained by intersecting the curve with its reflexion through the origin

GEOLOGY

Terrestrial Origin of the Igast Objects

THIS communication presents evidence for the terrestrial origin of the objects which allegedly fell from the sky at Igast, Estonia, in 1855 (ref. 1).

The Igast objects have been of interest in relation to the tektite problem, because if it could be proved that they were of extraterrestrial origin, they would be the first such material with the chemical composition of a tektite. It was suggested by us[2] that, since much of the Igast material referred to in published papers could be shown to be spurious, the genuine Igast specimens should be re-examined. Through the courtesy of Dr. M. Hey and Mr. M. Frost of the British Museum (Natural History) we were able to make a re-examination of specimen No. 36271 (British Museum (Natural History) number).

The specimen, which is part of the British Museum (Natural History) collection of pseudo-meteorites and is so labelled, weighs about 1·5 g. It is brownish lavender in most places, but is reddish-brown in a zone a few millimetres deep along one side and around some of the vesicles. The material is chiefly vesicular glass, but under the microscope can be seen to grade into a sintered mass of quartz grains. Several individual quartz grains and clusters of quartz grains are present.

The specimen examined is definitely one of the original ones collected by Grewingk and Schmidt (1864) as shown by its resemblance to their description and by the Museum label, which shows that it was acquired in 1864 directly from Grewingk. (In the 1880's the Russian dealer, J. Siemaschko, distributed specimens labelled Igast which were not acknowledged by Grewingk and were entirely different in their characteristics.) However, the specimen was completely fused in the Earth's atmosphere rather than being superficially melted, as are

meteorites. Evidence for this conclusion consists of the presence of abundant iron oxide throughout the specimen and the absence of a fusion crust. There is a smooth quenched skin which might be mistaken for a fusion crust, but is clearly not one because it grades into, and is identical with, the smooth surface lining vesicles.

This Igast specimen closely resembles the pseudoscoria formed by burning coal and lignite beds, such as described by Lydon[3] and others. It particularly resembles material discovered by Elbert A. King in Eocene sediments of the coastal plain near Huntsville, Texas, and shown by field relations to have been formed by burning lignite seams. Such material is much more common than formerly realized, since numerous specimens have recently been recovered from Iowa and surrounding states in a search for possible extraterrestrial materials resembling the Igast objects (Table 1).

Table 1

	Igast[1]	Iowa *W*-9	Iowa *W*-21

Metamorphic Differentiation in Crenulated Schists

It has recently been suggested by Rast[1] that the common development of modal variation in structures of the strain-slip[2] or crenulation cleavage[3] variety in quartz–mica schists is essentially a matter of mica recrystallization in "the points of maximum flexure" of the earlier developed schistose fabric. I suggest, however, that on the contrary in most cases the mobile constituent is silica, and that it is the recrystallization of quartz that is the basis of this type of metamorphic differentiation.

Such a view has been expressed already by Voll[4], who attributes a high surface energy to the junction of quartz and mica compared with quartz/quartz junctions or quartz and other minerals. In line with these views of Voll and the petrographic evidence, it seems reasonable to suppose that where a schistose quartz–mica rock is folded and develops zones of steeply dipping and highly strained schistosity in one set of limbs of asymmetric folds, the quartz diffuses from these zones and migrates to more gently dipping and less strained limbs and crystallizes there.

The typical crenulated schist contains asymmetric folds resembling kink-bands[5] and shows mica concentration not where there is the greatest flexure of first generation mica, as claimed by Rast, that is, along fold axial planes, but in the alternate limbs of the folds. Comparison of such rock with that in which the crenulation structures are not developed shows that the mica proportion in broad and only moderately rotated limbs is very close to the proportion in rocks without the crenulations, but that the narrow and strongly rotated limbs show pronounced deficiency of quartz. In thinly layered quartz–mica schists, quartz-rich layers may be followed into the steep limbs of such folds to thin greatly as the mica-rich layers on either side almost merge, but to thicken as the next broad limb is reached.

It is characteristic of mica-rich zones such as those of the folds of Fig. 1 to have as good a schistosity as limbs rich in quartz, and there is no difficulty in explaining the precise continuity of mica fabric by proposing silica migration and quartz recrystallization as, throughout the folds, the mica fabric is an arrangement directly inherited from an earlier phase of deformation and crystallization. In a hypothesis of mica recrystallization, however, there is more difficulty, as the common situation of Fig. 1 would then suggest the need for a very strict control of the attitude of the new micas, the crystallization of which supposedly took place only under the control of residual stresses[6]. This is not to say that the diffusion of micaceous

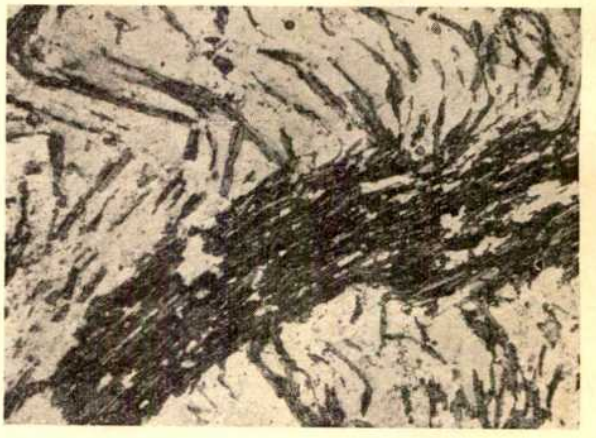

Fig. 1

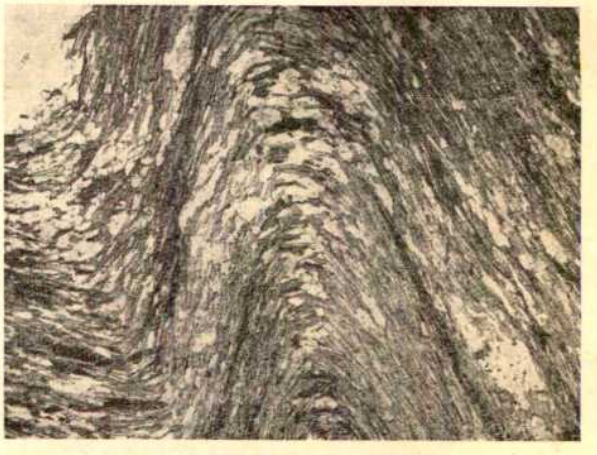

Fig. 2

components does not take place, but that these common cases of differentiation do not seem to show it. The hypothesis of quartz migration allows in addition a ready explanation of the development of differences of quartz fabric in the two limb types of asymmetric folds where grains in the two limbs often are of a different shape[7,8]. Thus, difference in mineral shape accompanies mobility of constituents.

Fig. 2 shows a rock in which crenulations are almost symmetrical. Here there is no formation of fold limbs alternately rich in quartz and in mica, but instead of quartz-rich zones along the axial plane traces. Here it seems that, since all limbs lay equally obliquely across the principal stress and were equally strained, silica-seeking areas of minimum strain concentrated in the fold hinges.

Thus the petrographic evidence is in favour of silica migration and quartz recrystallization rather than mica recrystallization as this allows crenulation differentiation (a conclusion suggested by Dewey[8] for kink bands). The ready diffusion of silica in a schistose quartz–mica fabric during deformation thus seems to be a most important element in the metamorphic differentiation of such rocks, and post-kinematic mica recrystallization is relegated to a role in developing other mica arrangements not possessing the continuous and well-marked schistose arrangement common to those illustrated here.

CHEMISTRY

Fluorescence Quantum Yield of 1-Dimethylaminonaphthalene-5-sulphonate

Fluorescence quantum yields may be determined with spectrofluorometers simply by comparing the corrected emission spectrum of an unknown substance with that of a compound of known fluorescence yield[1], provided that the relative numbers of photons reaching the solutions are known. Recently, 1-dimethylaminonaphthalene-5-sulphonate (DNS) in water at 25° was used by Churchich[2,3] as a fluorescence standard which was assumed to have a quantum yield of 0·53 as reported by Weber and Teale[4]. The assumption that this quantum yield figure was correct was also made by Slayter and Hall[5] for the purpose of calculating the efficiency of energy transfer in protein-dye conjugates. The purpose of the present communication is to direct attention to the fact that while DNS may be a suitable fluorescence standard, the quantum yield figure of 0·53 is incorrect. In fact, Bowen and Seaman[6] have already published data indicating that the quantum yield of DNS in water at 20° C is only about 0·29. These authors found that the quantum yields were higher in solvents of lower dielectric constant and took pains to exclude oxygen quenching by purging the solutions with a stream of carbon dioxide. Measurements of DNS quantum yield have been performed recently in this laboratory.

An Aminco-Bowman spectrophotofluorometer (American Instrument Co., Silver Spring, Md.) was calibrated by modifications of standard techniques (see ref. 7); and the fluorescence quantum yields were measured by comparison with quinine—it is well established that the latter has a quantum efficiency of 0·55 at 25° C in 1 N sulphuric acid[1,8]. The apparatus and its associated instrumentation have been described previously[9,10].

Table 1. Quantum Yields of 1-Dimethylaminonaphthalene-5-sulphonate at 23°

Solvent	Q
Water (purged with N_2)	0 37 ± 0·01
0 1 M $NaHCO_3$	0·36 ± 0·01
0·5 M $NaHCO_3$	0 33 ± 0 01
1 0 M $NaHCO_3$	0·31 ± 0·01
95 per cent ethanol (purged with N_2)	0 72 ± 0 02

The results obtained are shown in Table 1. DNS was found to have a quantum yield of 0·37 in water, but the fluorescence was quenched in bicarbonate solutions. The value $Q = 0{\cdot}31$ in 1 M sodium bicarbonate is reasonably close to that reported by Bowen and Seaman[6], so it can be assumed that their low figure was due to quenching as a result of the use of carbon dioxide to purge their solutions of oxygen. These authors also showed that the quantum yield of DNS in ethanol at 20° C, also purged with carbon dioxide, rose to about 0·75. This figure compares well with our measurements in ethanol purged with nitrogen. In ethanol, then, there is no appreciable quenching by carbon dioxide. Since the solubility at 25° C of carbon dioxide in ethanol is about four times that in water[11], the quenching observed in aqueous solutions is probably due to the HCO_3^- species.

DNS in 0·1 M sodium bicarbonate has now been used in this laboratory as a fluorescent standard ($Q = 0{\cdot}36$), and the results are the same as those obtained when quinine is used as the standard. DNS is easily crystallized, reasonably stable, and there is little overlap of the absorption and emission bands. Experience with our instrumentation leads us to agree with Parker and Rees[1] that determinations of quantum yield utilizing a comparison with a standard are probably more accurate than 'absolute' methods which attempt to measure Q directly.

Cadmium-109 in New Zealand Rainwater

Cadmium-109 has been detected in rainwater collected at the Institute of Nuclear Sciences site, Lower Hutt, New Zealand. This isotope is presumed to have been produced during the high altitude nuclear detonation, 'Starfish Prime', carried out over Johnston Island on July 9, 1962. The cadmium-109 was introduced at an altitude of 400 km to investigate distribution and fallout for debris injected at the outer edge of the ionosphere[1].

Cadmium-109, which has a half-life of 470 days, decays by electron capture to silver-109*m* ($t_{\frac{1}{2}} = 40$ sec). In the experiments to be reported the specific activity of the cadmium-109 in the samples was determined by measurements on the 22–25-keV *K* X-rays which follow the electron capture process and which also arise from internal conversion of the 88-keV radiation in the decay of silver-109*m*.

Measurements have been made on monthly rainwater samples collected between April and October 1964. Initially samples were collected in a stainless steel vessel; this was later supplemented by a polythene-lined tray. Both vessels yielded similar activities in the October collection, but the September results are significantly

different. The reason for this discrepancy is not yet understood. At the beginning of each month the bottoms of the collectors are covered with distilled water and appropriate carrier solutions added for the radioisotopes now being examined (caesium-137, strontium-90, barium-140, cerium-144, cerium-141, cadmium-109). For cadmium-109, 10 mg cadmium as sulphate is used. At the end of the sampling period, the rainwater containing the carriers and their associated activities is transferred to the laboratory where the cations are absorbed on 'Dowex 50 × 8' cation exchange resin at 80° C. To remove cadmium and the alkali metals, the resin column is eluted with 0·7 M hydrochloric acid and cadmium is associated with sodium in the early part of this elution. The cadmium fraction is evaporated to dryness and the residue redissolved in 0·25 M hydrochloric acid. Cadmium is then precipitated as sulphide by passing hydrogen disulphide through the solution. The precipitate is coagulated by heating on a water bath, and filtered on to a tared 1-cm diameter No. 42 Whatman filter paper disk, dried with acetone, and re-weighed. The filter paper disk and cadmium sulphide deposit is sealed by covering with transparent plastic tape. Blanks have been prepared from the carrier solution.

Since November 1964 no cadmium has been recovered because an unusually large amount of calcium, which was present in the rainwater, caused the cadmium to be removed from the 'Dowex 50' resin column during the cation absorption process.

The counting technique has been improved during the course of the work to be reported; the following procedure is now being used. To minimize errors which could arise from background variations a sample changer is used; this alternately moves a sample and a blank into the counting position. The pulses from the detector are routed to different segments of a pulse height analyser, the appropriate segment being determined by the position of the sample changer; sample changes are made every 40 min. Counting is carried out using a 0·080 in. thick × 0·5 in. diam. NaI(Tl) detector and a 14 stage photomultiplier. An X-ray spectrum from a 148-l. rainwater sample collected during October 1964 is shown in Fig. 1. This spectrum was obtained from a 2,040-min run with the counting time equally divided between sample and blank.

In an attempt to prove that the photopeak shown in Fig. 1 does indeed arise from cadmium-109 the October rainfall sample was ignited to remove the filter paper and plastic tape covers. The residue was digested with a few ml. of aqua regia on a water-bath and finally taken to dryness on a hot plate. The residue was dissolved in 0·25 M hydrochloric acid and cadmium precipitated as sulphide. The precipitate was filtered on to a tared 1-cm diameter No. 42 Whatman filter paper, dried with acetone and re-weighed. The cadmium sulphide deposit and filter were sealed with plastic tape. The specific activity of the treated sample was essentially the same as the original.

Identification based on the decay of the samples is being carried out. Measurements were made on the April sample during July and August 1964 and again in February 1965. During the intervening period the activity had decayed by a factor of 0·807 ± 0·153 which is in good agreement with the factor 0·766 obtained assuming a 470-day half-life.

Table 1

Collection date	Collector	Volume of rain water (l.)	Cadmium carrier recovery (per cent)	Fraction of total deposition	Activity (counts/min/l.)
April 1964	Stainless steel	41·2	81	1	0·185 ± 0·010
May 1964	Stainless steel	69 4	87	1	−0·002 ± 0·015
June 1964	Stainless steel	81 3	100	0 66	0 014 ± 0·015
July 1964	Stainless steel	75·2	100	0·44	0 031 ± 0·015
August 1964	Stainless steel	115·8	41·2	1	0 075 ± 0·015
September 1964	Poly-thene	157·0	84	1	0 097 ± 0·006
	Stainless steel	147·8	100	1	0·047 ± 0·006
October 1964	Poly-thene	42 9	21·8	1	0·204 ± 0·030
	Stainless steel	40·4	100	1	0·220 ± 0·014

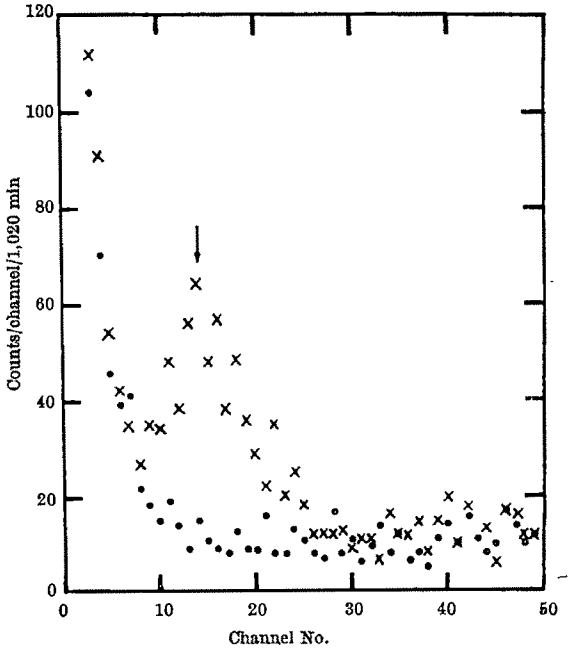

Fig. 1. Pulse height spectra obtained from September 1964 rainwater sample (×) and blank (●). The arrow indicates the expected position of the X-ray peak from cadmium-109

The results obtained so far are listed in Table 1. The results have been corrected for decay of the samples between collection time and counting. In evaluating the correction factor we have arbitrarily assumed that all the sample was collected on the first day of the month. The efficiency of the γ-ray spectrometer was determined using a cadmium-109 source kindly provided by the Health and Safety Laboratory, U.S. Atomic Energy Commission, New York.

The activity concentrations of the measured samples are of the order predicted by Salter[1].

Crystallization Kinetics of 1 : 3 : 5 Tri-α-naphthyl Benzene

Some years ago an examination[1] of the physical properties of tri-α-naphthyl benzene revealed that this compound exhibits unusual behaviour, spontaneously forming a hydrocarbon glass on cooling. It was also noted that the pure material (which is non-polar) could also be crystallized with difficulty. Recently, more extensive investigations of the physical properties of this material have led to significant results, particularly in relation to the nature of the transport phenomena experienced in viscous flow and crystallization.

A detailed investigation has been made of the kinetics of crystallization, from temperatures a few degrees below the melting point (T_m = 472° K) to within 25° of the glass transition temperature (T_g = 342° K). Over this interval a gradual transition in morphology, ranging from single crystals to spherulites, is observed as the temperature is lowered. The crystal growth rate varies over six logarithmic decades in this temperature span and passes through

a maximum at $T_{max} = 448°$ K. Viscosity measurements[2] (covering fifteen logarithmic decades in viscosity) made through the same temperature range have enabled us to test the validity of some aspects of accepted theories of crystallization[3,4] according to which the crystal growth rate, G, is given by:

$$G = G_0 \exp - \Delta F^*/kT \exp - \Delta G^*/kT \qquad (1)$$

Here G_0 is a parameter considered constant, ΔF^* represents the activation energy characteristic of transport across the liquid-crystal interface (usually taken as the activation energy for viscous flow in the liquid). ΔG^* is a measure of the energy required to construct a stable nucleus of the appropriate geometry.

We find that a model invoking coherent surface nucleation[4] is adequate for our analysis. In this model, B is a constant and the undercooling, $\Delta T = T_m - T$. The transport term, rather than having the form for an activation process, is better represented by a Vogel relationship[5]. This relationship is derived from, and is compatible with, free volume concepts. Under these changes, equation (1) becomes:

$$G = G_0 \exp\left(-\frac{C}{T - T_\infty}\right) \exp\left(\frac{-BT_m}{T\Delta T}\right) \qquad (2)$$

By a Williams–Landel–Ferry analysis[6] of the crystal growth at large supercoolings between T_g and T_{max}, values of the constants C and T_∞ are obtained. Then rearranging equation (2) and plotting $\log G + \frac{C}{2{\cdot}303(T - T_\infty)}$ versus $1/T\Delta T$ gives an approximate value for B. With this derived value of B, the temperature dependence of the transport process involved in crystallization can be written as $G' \equiv G \exp\left(\frac{BT_m}{T\Delta T}\right)$. With these G' values, a more accurate estimate of C and T_∞ is made. In turn, a better value of B is obtained. Utilizing the deduced constants from this truncated iterative process, we find that we can fit all the crystal growth data by equation (2).

Fig. 1 shows reduced plots for G' and viscosity data over the same temperature interval. The temperature dependence for viscous flow and transport-dominated crystal growth G' differ substantially. The present study clearly demonstrates that it is not correct to use the temperature dependence of viscous flow to describe the crystal growth of 1 : 3 : 5 tri-α-naphthyl benzene.

Over the temperature range where a free volume expression fits the results, the calculated parameters[7] for viscous flow are $b = 5{\cdot}0$, $v_0 = 0{\cdot}807$ c.c./g and $T_\infty = 200°$ K; for crystal growth $b = 0{\cdot}84$, $v_0 = 0{\cdot}848$ c.c./g and $T_\infty = 300°$ K. Here b is the Doolittle parameter[8] and v_0 is the occupied volume[6,10]. According to Cohen and Turnbull[10], b is a measure of the minimum hole size necessary for mass transport. The fact that b for viscous flow is the larger indicates that more co-operative interactions are necessary for flow than for crystal growth. If T_∞ is the temperature where the effective free volume for a process disappears (under equilibrium liquid volume which is unattainable in reality), then it may be concluded that between 200° and 300° K viscous flow is possible, whereas crystal growth is not. In contrast, at higher temperatures (Fig. 1), where b is the dominating influence in determining the severity of the temperature dependence, then mass transport in viscous flow changes more rapidly than it does in crystal growth. It appears reasonable that v_0 for crystallization should be the larger because the crystal substrate is space-consuming and thereby lowers the local probability for density rarefactions near the crystal interface.

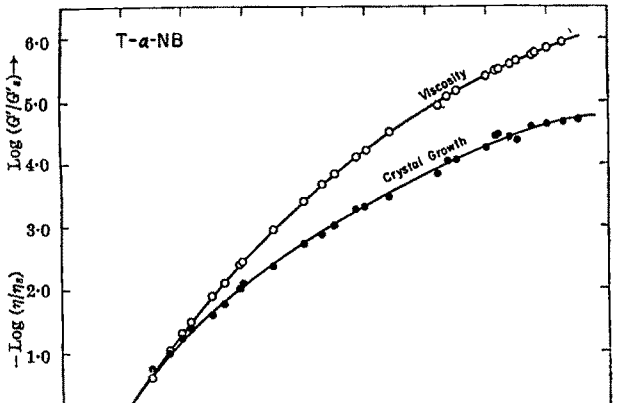

Fig. 1. Temperature dependence of reduced viscosity and transport dominated crystal growth rate of 1 : 3 : 5 tri-α-naphthyl benzene (reference temperature $T_s = 100°$ C). Subscript s indicates value of G' and η at T_s

Although these results apply specifically to a single compound, they may have implications relating to the behaviour of other crystalline materials.

Covalent Radii of Noble Gas Atoms and Position of Hydrogen in the Periodic System of Elements

In connexion with the discussion initiated in the article by Dash[1] on the position of hydrogen in the periodic system of elements, I wish to say that one cannot disagree with the critical notice of Hawes[2], who has stressed that it is not correct to express the 'atomic size' of members of the noble gas family in terms of their van der Waals radii (the only radii which are conveniently measurable) while for other elements (in the comparisons presented by Dash) covalent or metallic radii are used. Although, as Dash[3] has stated in his reply, the noble gas elements do not form homopolar covalent aggregates, the discovery during 1962–64 of a large number of noble gas compounds makes possible nowadays the estimation of covalent radii for these elements on the basis of their heteroatomic compounds. Such an attempt has been made by myself and colleagues[4].

First, the electronegativity (X) of noble gas elements has been computed using the Mulliken method and expressed in Pauling's scale according to the equation: $X = (I + A)/2 \times 2{\cdot}78$, where I is ionization potential, A, electron affinity. The following values have been obtained: $X_{He} = 4{\cdot}33$, $X_{Ne} = 3{\cdot}73$, $X_{Ar} = 2{\cdot}65$, $X_{Kr} = 2{\cdot}31$, $X_{Xe} = 1{\cdot}94$, $X^{Rn} = 1{\cdot}67$ (for comparison: $X_F = 3{\cdot}78$, $X_{Cl} = 3{\cdot}03$, $X_{Br} = 2{\cdot}77$, $X_I = 2{\cdot}47$, $X_O = 2{\cdot}71$).

Afterwards, using our own modification of Batsanov's[5] method, the averaged values of electronegativity ($\overline{\Delta X}$) and the averaged values of ionicity degrees ($\overline{i}$) have been computed for Xe—F and Xe—O bonds in the known

compounds XeF_n, and XeO_n, where $n = 1, 2, \ldots, 6$ (the degree of ionicity has been calculated by the Hanney and Smith equation: $\bar{i} = 0{\cdot}16\overline{\Delta X} + 0{\cdot}035\ (\overline{\Delta X})^2$; for the increasing n values the starting value of xenon electronegativity increases gradually, for example, from 1·94 in XeF to 2·16 in XeF_6, while $\overline{\Delta X}$ and $\bar{i}$ values decrease respectively). Then, using for the Xe—F bond-length the known Schomaker and Stevenson formula in the form:

$$r_{XeF(in\ XeF_n)} = r_{Xe(in\ XeF_{n-1})} + r_F - 0{\cdot}09\ |X_F - X_{Xe(in\ XeF_n)}|$$

and for the Xe—O bond-length an analogous formula, and also the experimental values of these bond-lengths in the species: XeF_2, XeF_4, XeO_3, XeO_6^{4-}, and the known covalent radius values of fluorine (r_F) and oxygen (r_O), the following values for the average covalent radius of xenon atom have been obtained:

$$\text{at single bond } r_{(Xe-)} = 1{\cdot}41\ \text{Å}$$

$$\text{at double bond } r_{(Xe=)} = 1{\cdot}18\ \text{Å}$$

The covalent radius of xenon (1·41 Å), computed in this way, is only about 6 per cent larger than that of the preceding element—iodine (1·334 Å). It seemed more reasonable to evaluate the covalent radii of the other noble gas elements analogically, that is, increasing the values for the preceding halogens about 6 per cent, than to assume, like Waters and Gray[6], that the formation of an octet causes no expansion of the electronic shell, or to add, like Nesbet[7], a constant correction 0·10 Å to the covalent radius of halogen directly preceding the given noble gas element. The values of covalent radii, estimated in this way, are:

Ne	Ar	Kr	Xe	Rn
(0·76 Å)	(1·05 Å)	1·21 Å	1·41 Å	1·55 Å

Although these values are much less than those of van der Waals radii used in Dash's communication[1], in accordance with his expectation[3], taking into account such corrections does not change the general nature of periodic relationships shown by the atomic radii of elements plotted as a family of curves dependent on the principal quantum number. In particular, the slope of line halogen–noble gas element on Dash's graphs remains the same as that of line hydrogen–helium, and remains the reverse of the slopes for lines drawn for all the other pairs of *s* orbital elements (lithium–beryllium, sodium–magnesium, etc.). This supports the uniqueness of the first quantum shell emphasized by Dash. As is easily proved, besides the covalent radii and boiling points the melting points of elements, plotted as a family of curves dependent on the principal quantum number, also show the same regularities.

The other suggestions of Hawes[2], that one can find the specific properties of hydrogen that would make possible the comparison of this element with any desired element or family of elements in the Periodic Table, and particularly the suggestion of considering the hydrogen as a very light member of Group IV*b* (carbon family), seem only partly true.

The uniqueness of the 1*s* (ref. 1) position of hydrogen, justified by energy conditions (ionization potential and constant energy difference (CED) (ref. 8), cannot be called into question. Some similarity of hydrogen to carbon, but not to other elements of the carbon family, is expressed not only in the near electronegativity values ($X_H = 2{\cdot}1$; $X_C = 2{\cdot}5$ in Pauling scale), what has been stressed by Hawes[2], but mainly in the fact that only these two elements, unique in the Periodic Table, use in their compounds all their disposable orbitals in the appropriate for their principal quantum level. In the case of these two elements, their orbitals are exactly half filled. These conditions are not obeyed for heavier members of Group IV*b*.

Moreover, the electronegativity of carbon is very near to the arithmetical mean of electronegativity ($\bar{X}$) of extremely electropositive caesium ($X_{CS} = 0{\cdot}7$) and extremely electronegative fluorine ($X_F = 4{\cdot}0$). As shown by Haiduc[9] this is the condition of homoatomic as well as heteroatomic catenation. The former is shown only, beside carbon, by sulphur ($X_S = 2{\cdot}5$), selenium ($X_{SE} = 2{\cdot}4$), and iodine ($X_I = 2{\cdot}4$) in polyiodides; the latter is appropriate for about 65 pairs of elements of different electronegativities, but which obey the Haiduc condition $\bar{X} = 2{\cdot}5 \pm 0{\cdot}35$. Such catenation leads to the formation of chain and cyclic structures by alternation of elements. This capacity of carbon to form homogeneous chains, taken with the specific properties of hydrogen, means that carbon and hydrogen bind readily together, and form unusually numerous, nearly pure covalent, mother hydrocarbon systems, thermodynamically stable and moderately reactive. They provide the millions of organic compounds characteristic for the alive nature. The richness of forms which are known, uniform and simple (in sense of types of chemical bonds), has contributed to and exaggerated the role of electronic octet and binding pair (cf. ref. 10).

This is the limit of the structural similarity of carbon and hydrogen atoms, however; their physical and chemical properties differ from those expected for the true chemical analogue or homologues.

On the other hand, the structural similarity of hydrogens ($1s^1$) and halogens (ns^2np^5), and therefore also the similarity of their properties, as stressed by Dash[1,3], arising from the fact that these elements require attraction of one electron to get the especially stable even-electron noble gas configuration, seems to be proved.

Moreover, this can also be said of the uniqueness of the first quantum shell (H–He) as compared with whole periodic system, as well as of some uniqueness of the second shell (Li–Ne) as compared with the next ones. This is evident in the properties of second period elements sometimes very different from those of their heavier analogues. This is a consequence of the energetic relations, which manifest themselves, among other things, in the values of constant energy difference, CED, also computed by Dash (cf. Table 2, ref. 8).

Labelled Products from the Internal Radiolysis of Liquid Cyclohexane saturated with Tritium Gas

Although the fate of the secondary electron in the radiolysis of water has been discussed for many years, most workers have assumed that it returns to the parent ion in condensed saturated hydrocarbon systems and have interpreted radiolysis data in terms of excited molecules and free radicals. However, the occurrence of ion-molecule reactions in such systems has been discussed by Libby[1] and Williams[2], both of whom have put forward indirect evidence for such reactions[3–6]. The action of several solutes has been interpreted in terms of secondary electron scavenging[7–9], and Freeman[10] and Allen[11] have shown by conductivity measurements on irradiated *cyclo*hexane and *n*-hexane respectively that low yields of free electrons and hence positive ions occur. However,

direct evidence for ion-molecule reactions in such systems is still lacking.

*Cyclo*hexane is the most studied liquid saturated hydrocarbon system and yields the smallest number of radiolysis products. Ho and Freeman[12] in a careful investigation of pure *cyclo*hexane have recently found primary products which had hitherto evaded detection.

We have investigated by gas chromatography the products formed by self-irradiation of *cyclo*hexane/tritium mixtures in the liquid phase and present the results as being pertinent to both the foregoing topics.

0·3 ml. samples of *cyclo*hexane (< 0·001 mole per cent impurity) were saturated with tritium gas at 44 mm and kept in a glass capillary at room temperature for up to two days. Fractions 20 cm from the top of the capillary were transferred to a side limb under vacuum and 2 μl. samples injected into a Pye-Argon gas–liquid chromatograph with proportional counter and ionization chamber attached. Preliminary experiments showed that no gas phase products formed above the surface of the liquid diffused rapidly enough to interfere with the results.

No compounds other than the parent *cyclo*hexane were detected with the ^{90}Sr β-ionization mass detector of the Pye chromatograph, but numerous labelled products were identified with the radiation detectors. Silicone oil, di(2-cyanoethyl)ether, and benzyldiphenyl were used as stationary phases. Chromatographic analysis was carried out at 25° C, limiting detection of labelled products to molecules with less than ten carbon atoms. Not all the products have been identified, but a list of labelled compounds with relative peak areas normalized with respect to *cyclo*hexane is shown in Table 1.

Table 1

2-methylbutane	0 01
n-pentane	0 17
2-methylpentane	0 08
n-hexane	0 20
methyl*cyclo*pentane	0·02
(C_6)	0 07
*cyclo*hexane	1·00
methyl*cyclo*hexane	0·10
*cyclo*hexene	0·04
ethyl*cyclo*hexane	0·22
(C_8 or C_9)	0·15
(C_8 or C_9)	0 32
(C_8 or C_9)	0·32

Although accurate G values have not been determined, the total yields are well above 0·02 indicating that tritium recoil labelling can account for only a small fraction of the products, and therefore most of the labelling is caused by internal tritium-β radiolysis of the *cyclo*hexane.

The implications of these results are threefold:

(1) Free-radical mechanisms are not dominant in the labelling reactions in this system. In radiolytic investigations of *cyclo*hexane it has been found that *cyclo*hexyl radicals are by far the most abundant free radicals as shown by the fact that di*cyclo*hexyl and *cyclo*hexene are the major products[12,13]. Consequently, if the tritium labelling of all products in the system discussed here occurred by free-radical reactions the yield of labelled by-products relative to that of labelled parent should be at least one order of magnitude lower. We conclude that in the production of labelled by-products, free radical reactions are not dominant. Ion-molecule reactions seem the most likely source of such by-products.

(2) There are many more primary products than have hitherto been detected in radiolytic investigations conducted without the use of tritium. Although reaction with tritium would alter the reaction pathway of the various intermediates, the formation of the many labelled products indicates that there are many more primary products.

(3) Fragmentation of *cyclo*hexane occurs in the liquid. The formation of carbon skeletons other than C_6 demonstrates that to a small extent fragmentation involving the breaking of two or more carbon–carbon bonds occurs in the liquid (as well as in the gas phase as shown by the mass spectral pattern) in spite of the cage effect of neighbouring molecules.

BIOPHYSICS

3,2,1 : *A,B,C* Sub-unit Hypothesis for the α-Chains of Tropocollagen

The clear-cut demonstration by Piez[1] that the 3 α-chains of cod-fish skin tropocollagen are unique, and the likelihood that a similar condition is true for all species of tropocollagen, have led me to consider various simple arrays of sub-units within the chains which could explain their known compositional features. I have arrived at a model in which an α-chain consists of 6 sub-units, each of approximately 17,000 molecular weight, and falling into 3 different compositional types that I call A, B and C, respectively. A tropocollagen unit, then, in this model would consist of a total of 18 sub-units: $6A$, $6B$, $6C$. Of all the possible combinations of 6 sub-units of 3 types in an α-chain, one which fits the known analyses of the amino-acid compositions of the several types of α-chains in the various tropocollagens is the following:

$$\alpha_1 = 3A+2B+C;\ \alpha_2 = 3C+2A+B;\ \alpha_3 = 3B+2C+A$$

For purposes of reference we designate this particular model as the 3,2,1 : *A,B,C* model, indicating that each different α-chain in the tropocollagen unit consists of a different array of the sub-units, but similar in that it has 3 of one kind of sub-unit, 2 of a second, and 1 of the third.

The validity of this model has been tested as follows: First, it must rationalize the data for the composition of the 3 separate chains of tropocollagen of cod-fish skin as determined by Piez. This is the most exacting test of the model because similarly complete data are not available for any other species of tropocollagen. Secondly, the model must be thoroughly consistent with the compositional data known for all the other tropocollagens examined which have been separated into α-chains. The reason why the data on these latter collagens are incomplete is that they have been separated into α_2 and 'α_1' chains, but the latter have not yet been experimentally resolved into α_1 and α_3 components as in the case of cod-fish.

In making such tests of the model, I have in particular determined how it accommodates the analysis with regard to 10 amino-acids, selected because each is present in a relatively low level in the tropocollagen molecule or is distributed unequally among the different α-chains. This constitutes the most stringent test of the model, since obviously less unique models could also explain the composition with regard to amino-acids which appear to be distributed in equal and large numbers among the different α-chains.

Before presenting the fit of the known amino-acid compositions with the proposed model, let us consider some of the ideas leading to its development. In this laboratory I have been impressed with the recurrence of the number 6, or multiples of it, as various chemical and physical aspects of the tropocollagen structure have been

* Calculated to a 100,000 molecular weight α-chain from experimental data of Piez (ref. 1).
† Calculated from the model $\alpha_1 = 3A+2B+C$; $\alpha_2 = 3C+2A+B$; $\alpha_3 = 3B+2C+A$ with integer amino-acid assignments to each of the sub-units.

analysed. Thus, there are 6 'ester-like' bonds per α-chain[2], and 12 hexose units per tropocollagen molecule[3]. Even more significantly, if one examines the amino-acid compositions of various species of tropocollagen as determined by Piez *et al.*[4], one is struck by the fact that amino-acids, critical according to the criteria already described here, occur in multiples of 6. Table 1 illustrates this circumstance for 5 amino-acids as they occur among 6 different tropocollagens. Thus, apart from the implications of the ester-bond and hexose analyses, there are reasons which compel one to consider a sub-unit hypothesis for the α-chains. (*Note added in proof.* Recently, Hörmann *et al.*[10] have shown the presence of an average of 6 N^{α}-acetyl residues per α-chain in tropocollagen and have interpreted this finding as consistent with an average of 6 sub-units per α-chain.) If one looks closely at the amino-acid compositional data, one sees that there is more regularity than contained in the simplest model that states that there are 3 different α-chains, 2 of which (α_1 and α_3) are similar but not identical in composition.

Recently, Blumenfeld *et al.*[5,6], using hydroxylamine-treated tropocollagen, have been able to isolate sub-unit fractions which are homogeneous in size. These fractions fall mainly into two molecular weight classes of about 18,000 and 34,000, respectively. Considering that the integral sub-units are 17,000 to 18,000 in molecular weight, a single α-chain of molecular weight approximately 100,000 would be comprised of 6 sub-units. Within the chain, of course, these sub-units could be covalently bonded so that after particular chemical or physical treatments they could be found as multiples of the 17,000 sub-units.

From the cod-fish skin tropocollagen α-chain analyses various models were calculated subject to the following rules: (1) There are 3 different kinds of sub-units of equal size. (Attempts to calculate models based on occurrence of 2 sub-units failed when they were unable to rationalize the amino-acid compositional data.) (2) Each α-chain contains 6 sub-units. (3) In the composite 3 chains (that is, the tropocollagen unit), there are equal numbers of each of the 3 sub-units. (Without this rule a great number of combinations becomes possible.)

The *A,B,C* α-chain models then can be classified as (6,0,0), (5,1,0), (4,2,0), (4,1,1), (3,3,0), (3,2,1) either for all three chains in a unified manner (for example, $\alpha_1 = 4A+B+C$; $\alpha_2 = 4B+A+C$; $\alpha_3 = 4C+B+A$) or in combinations (for example, $\alpha_1 = 4A+B+C$; $\alpha_2 = 3B+2C+A$; $\alpha_3 = 2B+3C+A$) in a non-unified manner.

Calculations were made for all unified models and only one model was found which could fit the data for the 10 selected amino-acids. Other models are able to fit some of the amino-acid analyses; however, none could fit as well as the unified (3,2,1) model below:

$$\alpha_1 = 3A+2B+C$$
$$\alpha_2 = 3C+2A+B$$
$$\alpha_3 = 3B+2C+A$$

In Table 2 are tabulated the experimental and calculated α-chain compositions for this model with various integer assignments to the *A*, *B* and *C* sub-units.

A striking result of this analysis is that the several sub-units are considerably more dissimilar than are the different α-chains. For example, the model predicts that a *B* sub-unit of the cod-fish tropocollagen should have 8 residues of lysine in contrast to 1 residue in the *C* sub-unit and 5 residues in the *A* sub-unit. Also, it predicts that histidine should be absent from the *A* and *B* sub-units and present to the extent of 4 residues in the *C* sub-unit. Outstanding differences in the distribution of other amino-acid residues among the several sub-units are also predicted, as seen in Table 2. These predictions can be tested when the *A*, *B* and *C* sub-units are isolated separately and analysed.

A different sub-unit model has been proposed by Petruska and Hodge[7] on the basis of interpretation of the electron optical appearance of various precipitated forms of tropocollagen and, in particular, of the segmental long-spaced form (SLS). This model consists of 17 sub-units per tropocollagen molecule. The sub-units are of two different sizes and compositions. An α_1- or α_3-chain is considered to have 5 sub-units, and an α_2-chain to have 7 sub-units. This model, although having certain interesting features, is not in agreement with several important chemical and physical features of the collagen structure.

The 3,2,1 : *A,B,C* sub-unit model proposed here explains much of the chemical data, and agrees with the size units found after treatment of tropocollagen with hydroxylamine. The predictions that it allows concerning the composition of the different sub-units (*A,B,C*—each of a molecular weight approximately 17,000–18,000) can readily be tested by isolation and analysis of the sub-units. Experiments towards this end, utilizing various tropocollagens, are now in progress in this laboratory.

Coacervate Behaviour in an Alternating Electric Field

Coacervates have been intensively investigated because of their presumed importance in the origin of life[1]; however, their electrical properties, representing many important processes, appear to have been relatively neglected. We

have continued work by Bungenberg de Jong[2] on the behaviour of coacervates in an alternating electric field, and effects similar to those reported by Heller and Texeira-Pinto[3] and Furedi and Ohad[4] on living cells have been observed.

Our work used gelatine–gum arabic and haemoglobin–gum arabic coacervates prepared by a method similar to that reported by Dervichian[5]. To prepare the gelatine coacervates, equal volumes of 1 per cent solutions of gelatine and gum arabic were mixed and brought to a *p*H range of 2·5–4·0 by adding sodium acetate-citric acid buffer. Coacervate formation could be seen by the appearance of a white turbidity as the mixture was acidified. The haemoglobin coacervates were formed by mixing two volumes of a 2 per cent haemoglobin solution (prepared by the lysis of red blood cells) with one volume of a 1 per cent gum-arabic solution and acidifying as above.

The electric field was applied to a simple assembly on a microscope slide. Brass strips 0·0125 cm thick separated from each other by a distance of 0·1–2 cm were used as electrodes. The brass strips were fixed to the slide by embedding them on melted 'Parafilm' sheets (manufactured by Marathon, Neeah, Wisconsin); the assembly was then allowed to cool, and a chamber was cut between the electrodes to enable direct contact to be made with the solution. The observations reported in this communication cover the frequency range from 4 c/s to 700 kc/s: the electric field intensity was a maximum of 500 V/cm.

Flattening of the gelatine–gum arabic coacervates, with the long axis perpendicular to the field, was observed throughout the frequency range. This response to the electric field was strongest during the first few minutes after the coacervates had formed. The minimum field strength necessary to obtain deformation increased at higher frequencies and higher *p*H ranges. After the field had been applied for several minutes, coalescence of these coacervates into streams perpendicular to the field occurred. When the coacervates were allowed to age for 15–60 min, the coacervate morphology changed and we could sometimes see a difference in the response to the electric field. The elongation became parallel to the electric field.

The haemoglobin–arabic coacervate behaviour in the electric field was also observed to be strongly dependent on time. When the coacervates were fresh, they flattened into discoidal shapes perpendicular to the field at all frequencies used and showed seemingly-random rotations. As the haemoglobin coacervates aged (about 1 min from the time of acidification) the perpendicular elongation disappeared and the only deformation observed was elongation parallel to the field and chain formation which occurred at the higher frequencies. These observations on the haemoglobin coacervates are very similar to those of Füredi and Ohad[4] on the living red blood cell. These authors found that an electric field of 120 Mc/s, applied to an isotonic sucrose suspension of erythrocytes, aligned the cell radii perpendicular to the field direction, and caused slow rotation. However, older cells (with regard to time of formation in the donor) became elongated in the direction of the field and formed chains parallel to the field. Our coacervates showed, to the living red blood cells, an analogous behaviour, when they first became elongated perpendicularly, then later parallel, to the field and form chains.

Füredi and Ohad explained their results by considering the electric field behaviour of elastic charged spheres. If the young cells had a lower dielectric constant than the medium and bear a surface charge, then their behaviour was accounted for. Older cells, having a higher dielectric constant and a lower surface charge density, would become elongated parallel to the field and form chains. This explanation would seem to be the most appropriate to explain the coacervate behaviour. We also expect that the frequency variation of deformation is connected with the finding of Schwan[6], who reported extraordinarily large dielectric constants of colloid suspensions at low frequencies.

Our observations as described here indicate that coacervates exhibit similar electrical behaviour in an alternating electric field to that of some living cells. The coacervates are, therefore, of interest as a model system for the study of the behaviour of living cells in electric fields.

BIOCHEMISTRY

Effect of Vitamin E Deficiency on Uptake of Amino-acid and Incorporation in Isolated Rabbit Diaphragm

One of the most striking effects of vitamin E deficiency is the acute muscular wasting seen in young rabbits raised on a tocopherol-free diet. Although this nutritional muscular dystrophy has been known for more than thirty years, its mechanism remains obscure. If impaired muscle protein synthesis were the cause of the wasting, one should expect that vitamin E-deficient animals would incorporate less of a given dose of amino-acid labelled with carbon-14 into muscle proteins when compared with vitamin E-supplemented animals. Surprisingly, Dinning *et al.*[1] have found that dystrophic muscle incorporated more glycine-1-^{14}C.

This does not necessarily mean that muscle protein synthesis is increased in this condition. Radioactivity from an injected dose of glycine-1-^{14}C or of α-aminoisobutyric acid-1-^{14}C (AIB) reaches the free amino-acid pool of muscle of dystrophic rabbits faster than that of vitamin E-supplemented animals[2,3]. Higher radioactivity of the amino-acid precursor should be expected to lead to a higher radioactivity of the proteins. *In vivo* investigations are further complicated by possible effects of the dietary deficiency on plasma volume, blood supply and capillary permeability. In order to exclude such complications, I have investigated the effect of vitamin E deficiency on amino-acid uptake by isolated rabbit diaphragm, and amino-acid incorporation into diaphragm proteins *in vitro*.

Two groups of four-week-old White New Zealand rabbits received a vitamin E-deficient semi-synthetic diet. One group was given oral supplements of α-tocopherol acetate. The composition of the diet and the manner of vitamin E supplementation and other details of animal care were the same as in previous experiments[3]. When symptoms of beginning muscular dystrophy (urinary creatine excretion and muscular weakness) became evident in the vitamin E-deficient group after approximately three weeks, animals were killed and diaphragms were quickly excised. Conditions of the incubation of hemidiaphragms with ^{14}C-labelled amino-acids are indicated in Table 1. At the end of the incubation periods the hemidiaphragms were briefly rinsed in ice-cold saline, blotted, weighed and homogenized. Total proteins of diaphragm incubated with glycine were precipitated with hot trichloroacetic acid (TCA) and lipids removed in the usual manner. Radioactivity was determined in the proteins and in the TCA-soluble extract.

Table 1 shows that vitamin E-deficiency caused a more than two-fold increase of incorporation of glycine-1-^{14}C

into diaphragm proteins. The result obtained *in vivo* by Dinning *et al.*[1] has thus been confirmed with isolated muscle. This increase may well be due to a higher specific activity of glycine in the precursor pool, as indicated by the higher activity found in the TCA extract.

Glycine is not very suitable for an investigation of amino-acid uptake because of its participation in numerous metabolic pathways. Christensen *et al.*[4] have therefore suggested to use the non-metabolizable AIB as a transport model. This amino-acid is not incorporated into proteins and it resembles glycine in its transport properties[5]. In the work recorded here the effect of vitamin E deficiency on amino-acid accumulation in skeletal muscle has been investigated with the aid of AIB. After incubation of hemi-diaphragms of vitamin E-deficient and supplemented rabbits with AIB-^{14}C the tissue was homogenized and extracted with hot 0·01 N acetic acid and radioactivity was determined in the extract.

The results (Table 2) are in line with those obtained with glycine and differences between the two groups of animals are even greater. After 1 h of incubation, diaphragms of vitamin E-deficient animals contained on the average 92 per cent more AIB-^{14}C. The observation that vitamin E-deficient muscle accumulated less glycine than AIB is probably due to the fact that some of the glycine is utilized for protein synthesis and carbon dioxide formation, the latter being greatly elevated in vitamin E deficiency[6]. Since distribution ratios in Tables 1 and 2 are expressed on a 'per gram of tissue' basis, one might suspect that a higher ratio could be caused by higher water content or greater extracellular space. However, earlier experiments have shown[3] that differences in water content and inulin space between skeletal muscle of vitamin E-deficient and of supplemented rabbits are small. They cannot account for the differences observed here. The same applies to diaphragm weights. Average hemi-diaphragm weight of vitamin E-supplemented animals was 644 mg, and of vitamin E-deficient animals 669 mg. This difference is not statistically significant. The content of TCA-precipitable protein was significantly lower ($P < 0·025$) in diaphragms of the deficient group: 10·2 per cent, versus 12·5 per cent in the supplemented group.

The experiments recorded here do not exclude the possibility that there is a higher rate of protein synthesis in skeletal muscle of vitamin E-deficient rabbits. They do indicate that the big increase in the rate of incorporation of glycine-1-^{14}C into muscle proteins of vitamin E-deficient rabbits is at least partly due to a higher rate of glycine uptake into the tissue amino-acid pool. The finding of increased amino-acid accumulation in vitamin E deficiency is of particular interest in view of the increased oxygen consumption of vitamin E-deficient muscle[7], and the reported linear relation between oxygen consumption and membrane transport in some tissues[8,9].

Table 1. Uptake of Glycine-1-^{14}C by Isolated Diaphragm and Incorporation into Proteins

(*A*) Specific activity of diaphragm proteins (c.p m./mg protein)

	1 h	2·5 h
Vitamin E-supplemented (9)*	69 ± 20†	188 ± 63
Vitamin E-deficient (9)	153 ± 75	474 ± 137

(*B*) Distribution ratio of TCA-soluble glycine (c.p.m./g diaphragm divided by c.p.m./ml. medium)

Vitamin E-supplemented (9)	0·63 ± 0·10	0 81 ± 0·20
Vitamin E-deficient (9)	0·91 ± 0 21	1·11 ± 0·23

* No. of animals in parentheses.
† Mean value ± standard deviation.
Statistical evaluation by the Student *t* test indicates that the differences between vitamin E-supplemented and deficient groups are significant ($P < 0$ 025) at both incubation times.
Conditions of incubation: Dubnoff metabolic shaker; 37° C; O_2–CO_2 atmosphere 95 : 5; 8 ml. Krebs-Ringer bicarbonate buffer *p*H 7·4, containing 4 μc. of labelled amino-acid. Specific activity of glycine: 4·84 mc./mmole.

Table 2. Uptake of α-Aminoisobutyric Acid-1-^{14}C by Isolated Diaphragm

	Distribution ratio (c.p.m./g diaphragm divided by c.p.m./ml. medium)	
	0·5 h	1 h
Vitamin E-supplemented (6)	0·46 ± 0 04	0·66 ± 0·12
Vitamin E-deficient (6)	0·66 ± 0 07	1·27 ± 0·46

See legend to Table 1 for explanation of terms and conditions of incubation. The difference between the two groups is significant ($P < 0$ 025) at both incubation times. Specific activity of AIB: 10 03 mc./mmole.

Determination of Serum Oxytocinase (*l*-Cystine-aminopeptidase) Activity

An increasing interest is being shown in serum oxytocinase (*l*-cystine-aminopeptidase (3.4.1.2.)) levels in pregnancy, yet the methods described in recent papers[1,2] for its determination seem unnecessarily laborious. We have for some time now been using the modification described here. It is based on the method used for the determination of *l*-leucine-aminopeptidase (3.4.1.1.) activity in serum[3–5], now used as a routine biochemical investigation for which commercial test kits have been developed, such as that of Boehringer, Biochemica, Mannheim, which we use.

The buffer is 0·05 M phosphate (KH_2PO_4 (Sørensen) and K_2HPO_4), *p*H 7·20. The substrate is *l*-cystine-di-beta-naphthylamide, 135 mg dissolved in hot 0·012 N HCl and made up to 100 ml. with H_2O. It is understood that preparations made with beta-naphthylamide are now known to be carcinogenic. Although opinions on the various concentrations required for harmful activity differ, we think that the particular concentration used here does not necessitate precautions other than usually employed in biochemical laboratories using often poisonous material. It is, however, the intention of the authors to replace the present substrate with a new preparation as soon as a manufacturer can be found to produce it routinely. The chromogen is diazotized 3-chloro-4-nitraniline (Echtrot '3 GL') 1 mg per ml. of H_2O.

The principle of this reaction of cystine aminopeptidase (CAP) is:

$$l\text{-cystine-di-beta-naphthylamide} + H_2O \xrightleftharpoons{\text{CAP}} l\text{-cystine} + \text{beta-naphthylamine}$$

The azo-dye produces a red colour with the enzyme-liberated naphthylamine which is extracted with ethyl acetate; its concentration is measured colorimetrically, and the CAP activity of serum is deduced. Since the liberation of naphthylamine is linear within the range of enzyme activity to be found in normal and abnormal human sera, a factor can be used for calculation of the enzyme activity per ml. of serum.

A mixture of 2·40 ml. of buffer and 0·01 ml. of substrate and 0·30 ml. of serum is incubated at 37° C for 1 h, and 2·50 ml. of trichloroacetic acid is added. After centrifugation, 1 ml. of supernatant is added to 1 ml. of chromogen, which then is mixed well and stood at room temperature for 10 min. 5 ml. of ethyl acetate is added and the tubes are shaken vigorously. The extracted colour intensity is measured in the ethyl acetate using a colorimeter at 546 mμ and a 1-cm light path rectangular cuvette against a blank prepared using H_2O instead of serum.

The absorbancy of the ethyl acetate is multiplied by the factor of 118 for calculating CAP activity per ml. of serum.

It should be pointed out that this factor needs to be corrected according to the variations in instrument sensitivity and other technical factors for individual laboratories by setting up an initial calibration curve of beta-naphthylamine.

Effects of Propiolactone on Rat Fibrocytes

B-PROPIOLACTONE has been reported[1–4] to be a potent but slowly acting carcinogen *in vivo*. In an investigation of the effects of this agent on rat fibrocytes cultivated *in vitro*, treated cells were found to undergo a particular sequence of structural alterations which culminated in cytological malignancy. This sequence of changes appeared to be directly related to the process of carcinogenesis.

Fibrocytes were grown from Wistar strain rat embryo voluntary muscle tissue. They were cultivated as monolayers on No. 2 coverslips in hexagonal roller-tubes. Suspensions of fibrocytes in modified culture medium were prepared either directly by dissociating the parent tissue with 0·25 per cent commercial grade trypsin in 0·9 per cent sodium chloride solution at 4° C overnight, or by the trypsinization of recently derived stock cultures grown from muscle explants. The latter method gave cleaner preparations. The density of cell population was adjusted to give thin, incomplete monolayers at the beginning of treatment. This made provision for subsequent proliferation. Coverslip cultures were fixed in Heidenhain's 'Susa' fixative for 10 min and routinely stained progressively with Ehrlich's acid haematoxylin and alcoholic eosin. Stained cultures were mounted under matching No. 0 coverslips for study with oil immersion objectives.

The normal culture medium, as used for control cultures, was composed of 25 per cent of inactivated calf serum, 55 per cent of tissue culture medium supplement No. 199, and 20 per cent of Earle's buffered saline solution. It also contained lactalbumin hydrolysate and extract of autolysed yeast at final concentrations of 0·25 and 0·1 per cent, respectively. Mycostatin at 50 units/ml., penicillin and streptomycin at standard concentrations were also incorporated in the medium. The original cell suspensions were prepared in this medium, to which was added either 5 per cent of cell-free sarcoma 37 ascites tumour 'plasma', or 0·25 per cent of heparinized rabbit plasma. The addition of plasma promoted adhesion of fibrocytes to the coverslips.

Experimental media were prepared by the addition of propiolactone to the normal culture medium and serial dilutions. After a preliminary cultivation for several days, fibrocytes were treated daily with concentrations of propiolactone ranging from M/10 to M/100,000 in a standard volume of 4 ml. per roller-tube. The lactone was rapidly inactivated in culture medium. At concentrations of from M/10 to M/500 propiolactone quickly killed the cells during the first application. Depletion of basophilic material from both nuclei and cytoplasm was noticeable even when structural detail was virtually 'fixed'. This loss was not secondary to autolysis but due to a direct effect of the agent. One application of M/1,000 propiolactone irreversibly injured the fibrocytes; those in mitosis were most susceptible. Fibrocytes withstood 2–3 applications of M/2,500 and 5–6 applications of M/5,000 propiolactone, but almost no viable dividing cells were found at any time. M/10,000 and M/20,000 drug concentrations were slowly lethal and most mitoses were abnormal. The margin of safety was difficult to estimate because of the delayed toxic effects. Mitotic aberrations were widely varied. They included failure of chromosomes to move to the metaphase position, spindle failure, incomplete separation and coalescence of metaphase chromosomes, anaphase bridges and deletions, and faulty telophase reconstructions. The majority of mitotic aberrations occurred at prometaphase; the chromosomes remained entangled and degenerated.

After about eighteen successive applications of M/40,000 propiolactone cytologically malignant cells appeared in treated cultures. These cells were very hyperchromatic, with deeply basophilic cytoplasm and indistinguishable from typical sarcoma cells. They proliferated rapidly. At this drug concentration treated cells responded with over-compensation to the repeated injuries caused by propiolactone. M/100,000 drug concentration was usually less effective than M/40,000 in inducing malignancy.

Comparisons of interphase cells treated with the graded drug concentrations showed a common pattern of qualitatively similar lesions which varied from the infliction of rapid cell death to the transformation of normal fibrocytes to viable, dividing malignant cells by a progressive adjustment to repeated slight injuries. The initial aberrations of mitosis appeared to be less directly relevant than the alterations in interphase cells to the carcinogenic process.

Structural changes in interphase cells of the foregoing pattern were initially shown by the loss of basophilic material from the cytoplasm and nuclear organelles. This loss was relatively slight in cells exposed to M/40,000 propiolactone solutions. It was well marked in the nucleoli and chromocentres. Cytoplasmic basophilia is positively related to the presence of RNA-containing ribosomes in ergastoplasm[5,6]. The parallel disappearance of basophilic material from the matrices of nucleoli revealed their internal reticular structure. The typical mammalian nucleolus consists of such a reticulum embedded in an optically amorphous matrix[7,8]. The component threads of the intranucleolar reticulum or nucleolonema[9] were thicker than those of the nuclear reticulum itself, but the threads of the two networks were structurally continuous. These altered primary nucleoli had a variable reticular structure associated with different amounts of matrix substance.

The early loss of basophilic matrix substance was followed by hypertrophy of the nucleolonema structure. This was brought about by a preliminary thickening of nuclear reticulum threads continuous with those of the nucleolonema before they were incorporated into the structure of the enlarging nucleolus. This thickening usually began with the development of small discrete nodes along a thread. These enlarged and became confluent to form a generally thickened thread. The nodes were sometimes confluent from their first appearance. Modified nuclear reticulum threads became indistinguishable from the original threads of the primary nucleolus and laid down matrix material.

Sections of nuclear reticulum unconnected with nucleoli similarly hypertrophied. In some cells these altered threads appeared to give rise to surrogate secondary nucleoli. Altered nucleoli reached their maximum development in the induced malignant cells and were rich in basophilic matrix substance. They were usually irregular in shape through the protrusion of hypertrophied reticulum threads which tapered into strands of nuclear reticulum. Chromocentres enlarged and became more numerous parallel with the changes in reticulum threads. The process of nucleolar enlargement continued to the fully malignant stage at which basophilia was maximal. The malignant cells multiplied rapidly, unlike the altering cells. The complete sequence of alterations was readily followed in fibrocytes treated with M/40,000 propiolactone.

Comparison of sister cells in the reconstruction phase of the nuclei showed a detailed similarity in the pattern of altered reticulum threads of the twin nuclei. However, variation in pattern between different pairs of sister nuclei was great. This suggested that the changes were inherited. The latter continued to develop during interphase and probably gave rise to chromosome abnormalities during mitosis.

The nucleolus is regarded as the main site of development of ribosomal RNA (refs. 7, 8 and 10) and is positively correlated with protein synthesis and cell growth[5,6] which are dependent on the ribosomes of ergastoplasm. Replacement of cytoplasmic RNA in fibrocytes injured by propiolactone would seem, therefore, to be dependent on the restitution of nucleolar function, itself decreased by the carcinogen. The latter was achieved by conversion of sections of nuclear to nucleolar reticulum. This transformation of portions of nuclear reticulum implied the converse loss of their original functions. The nuclear reticulum and its associated organelles comprise the interphase equivalent of formed chromosomes. The carcinogenic action of propiolactone would therefore seem to be related to the progressive development of increased growth potential at the expense of losing specific chromosomal functions. The characteristics of malignant cells are in accordance with this interpretation.

Methionine-activating Enzyme and Catechol-O-methyl Transferase Activity in Normal and Leukaemic White Blood Cells

It has been found recently in these laboratories that the leucocytes of patients with chronic myelocytic leukaemia have significant elevations of the important methyl donor, *S*-adenosylmethionine (SAMe) (ref. 1).

The original series of patients has been extended to include 40 leukaemic and 20 normal leucocyte preparations. Not only is there an elevation of SAMe in chronic myelocytic leukaemia, but there also appears to be a decline of this substance with remission of the disease[2]. The mechanism and significance of this abnormal biochemical finding are not clear and are now under investigation here. The work recorded here was designed to discover whether the SAMe-synthesizing enzyme or a methyl transferase can be detected in human leucocytes. In addition, since SAMe elevation could be due to increased synthesis or decreased utilization, the examination of these enzymes might help explain the elevations in SAMe noted.

Blood was obtained from 14 untreated patients with chronic myelocytic leukaemia at the National Cancer Institute. Our diagnoses were confirmed by haematological and cytogenetic examinations of peripheral blood and marrow. Total peripheral white counts ranged from 50,000 to 350,000 cells/mm^3, and all patients had elevations of immature peripheral white blood cells. Leucocytes were also obtained from 19 normal blood donors for comparison with leukaemic cells.

The white blood cells were isolated by plasmapheresis followed by dextran centrifugal sedimentation and osmotic stress at 4° C by the method of Fallon *et al.*[3]. The concentrated white cells were stored at −20° C until assayed for enzyme activity, usually within 48 h. With careful preparation, it was possible to obtain 1 g of white cells from 500 ml of normal whole blood. Aliquots of leukaemic cell preparations of the same quantity (1 g) were taken. Leucocyte homogenates were prepared by homogenizing aliquots of the frozen wet white blood cell preparations in 5 vol. of ice-cold isotonic potassium chloride and centrifuging at 0° C, 10,000*g*, for 30 min.

The activity of a typical and ubiquitous methyl pherase, catechol-*O*-methyl transferase (COMT) (ref. 4), was measured by a modification of a previously reported assay of the combined activity of methionine-activating enzyme (MAE) and COMT (ref. 5). Dihydroxy benzoic acid was converted to vanillic acid-methoxy-^{14}C with SAMe-^{14}C (New England Nuclear Corp., Boston, 40 c./mole) in tubes containing 1 μmole of substrate, 52 mμc. of SAMe-^{14}C, 50 μmoles of magnesium chloride, 125 μmoles of phosphate buffer (*p*H 7·8), and 0·5 ml. of the leucocyte preparations. The mixture was incubated for 30 min and ^{14}C-vanillic acid was extracted into ethyl acetate from the strongly acidified reaction products. The products, labelled with carbon-14, were assayed by liquid scintillation spectroscopy[6]. The extracted carbon-14-labelled product, in excess of a boiled enzyme blank, varied linearly with both incubation time and enzyme concentration.

The activity of methionine activating enzyme in the leucocyte homogenates was estimated by the method of Mudd *et al.*[7], utilizing the synthesis of SAMe-^{14}C from methionine-^{14}C and ATP, and isolation of SAMe-^{14}C on 'Dowex-50-NH_4^+' chromatographic columns. The carbon-14 eluted by ammonia varies linearly with incubation time and enzyme concentration.

Table 1. Enzyme Activities in Normal Human Leucocytes and in Chronic Myelocytic Leukaemia (CML)*

	Normal	CML	
N	19	14	*P*
MAE	3·59 ± 0·75	4·78 ± 1·06	0·3–0·4
COMT	6 05 ± 0·51	5·04 ± 0 97	0·3–0 4

* MAE = methionine activating enzyme, units ± *S.E.* COMT = catechol-*O*-methyl transferase, units ± *S.E.* Unit enzyme activity equals mμmoles of product formed in 30 min per gram of frozen wet leucocytes. *P* is probability by 'Student' *t*-test, *N* is the number of patients.

The results of these enzyme assays are presented in Table 1. They demonstrate that human leucocytes contain detectable quantities of methionine-activating and methyl transferase activity. In chronic myelocytic leukaemia, these enzyme activities are not different from normal.

The significance of methylation in leukaemia has not yet been adequately evaluated. In addition to the finding of increased levels of SAMe in leukaemic white cells[1], other facts are presently available to suggest that abnormal methylation may be of importance. Folic acid is increased in leukaemic cells[8], and antifolate agents have been used in leukaemia chemotherapy. Patients with chronic myelocytic leukaemia have increased amounts of vitamin B_{12} in their serum[9,10]. Finally, methionine activating enzyme and COMT appear to be normal in chronic myelocytic leukaemia leucocytes. Thus it is not clear whether SAMe is elevated in chronic myelocytic leukaemia cells because of increased synthesis or decreased utilization. There are many routes of utilization[11,12] which remain to be studied and which might be decreased. Elevations of SAMe have been demonstrated in the presence of normal MAE activity[13] when methionine availability is increased[14]. Methionine might be more readily available for SAMe synthesis if its entry into leucocytes were increased or its incorporation into protein were decreased. Assays of leucocyte methionine are thus in order. The suspected decrease in leukaemic white cell ATP degradation[15] is of uncertain significance for SAMe synthesis.

Reduced Nicotinamide-adenine Dinucleotide and Pyruvate in Urea-denaturation of Lactic Dehydrogenase Isozymes

IT has recently been reported that lactate dehydrogenase isozymes differ from each other in denaturation caused by urea[1-4], probably depending on the different resistance of the sub-units in these isozymes against denaturating forces. The aim of this contribution is to show that the presence of coenzyme during urea incubation may help to differentiate isozymes composed of different sub-units, and that the increase of substrate molarity will further accentuate this differentiation.

The isozymes examined were LDH_1 (pig heart) and LDH_5 (rabbit muscle) received from Boehringer and Soehne, Mannheim. The determinations of LDH activity were made in duplicate as presented earlier[4] and were confirmed with repeated measurements. Urea concentration selected was 1·5 M, at which molarity we have noticed the greatest difference between these isozymes. Pyruvate concentrations used were $2{\cdot}5 \times 10^{-4}$ M and 10×10^{-4} M. NADH concentration was $1{\cdot}3 \times 10^{-4}$ M in all determinations.

In our first experiments we used $2{\cdot}5 \times 10^{-4}$ M pyruvate. As seen in Fig. 1*A* the incubation of LDH_1 in urea solution without pyruvate and NADH diminished the enzyme activity to 54 per cent. The presence of pyruvate during the incubation did not prevent denaturation (56 per cent), but when the enzyme was incubated with urea and NADH the activity remained at 64 per cent. The presence of NADH during incubation thus protected the activity of LDH_1 about 20 per cent. On the contrary the inactivation of LDH_5 in this urea concentration was not prevented by NADH. The activity of LDH_5 was already diminished to about 5 per cent in all incubation arrangements (Fig. 2*A*).

In order to see whether substrate concentration has an effect on the inactivation caused by urea the determinations were made with four times greater pyruvate concentration (10×10^{-4} M). The activity of LDH_1 incubated with urea solution in the absence of pyruvate and NADH was 70 per cent; in the presence of pyruvate, 69 per cent; but in the presence of NADH, 85 per cent, as shown in Fig. 1*B*. The protective effect of NADH against urea denaturation was the same (about 20 per cent) as in the lower pyruvate concentration. At the higher pyruvate concentration the increase of enzyme velocity was about 30 per cent in all incubation arrangements. As with the lower pyruvate concentration, the protective effect of NADH on LDH_5 was not evident at the higher concentration (Fig. 2*B*), and the enzyme velocity was not increased as compared with the lower pyruvate concentration.

The results observed here show that the presence of NADH during incubation favours the maximal difference between lactate dehydrogenase isozyme activities because it counteracts the inactivation of LDH_1 but does not seem to have this effect on LDH_5 at this urea concentration. The increase of pyruvate molarity also favours this effect. We have also noticed these same effects with human LDH isozymes, which is in accordance with our earlier study[4] where no major difference could be seen between the animal isozymes and human isozymes separated electrophoretically. Hardy[3] has recently presented a method for separation of LDH isozymes in clinical use. He incubated the enzyme with NADH during 2·6 M urea treatment and used $3{\cdot}1 \times 10^{-4}$ M pyruvate.

Coenzymes (NADH and its analogues) have earlier been shown to protect heart lactate dehydrogenase against various inactivating agents, and this protection has been thought to be mediated by the formation of

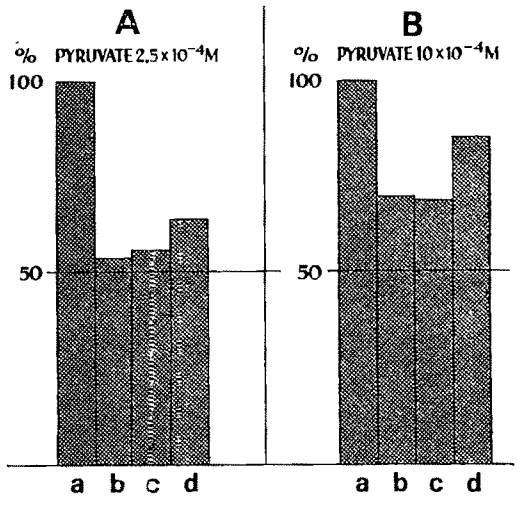

Fig. 1 *A*, Determinations made with substrate pyruvate concentration of $2{\cdot}5 \times 10^{-4}$ M. NADH concentration was $1{\cdot}3 \times 10^{-4}$ M in all determinations and the reaction was carried out in phosphate buffer of *p*H 7·4. (*a*), LDH_1 activity without urea inactivation. The activity of LDH_1 after 10 min incubation with 1·5 M urea when (*b*) the urea incubation was made without pyruvate and NADH, (*c*) the incubation in the presence of pyruvate, (*d*) the incubation in the presence of NADH. *B*, The diagrams are made as above but with pyruvate concentration of 10×10^{-4} M

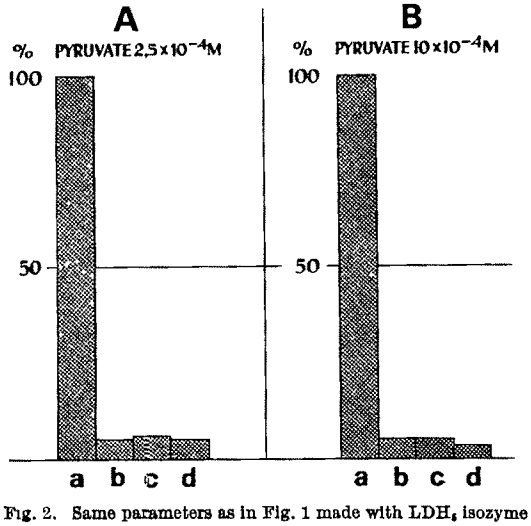

Fig. 2. Same parameters as in Fig. 1 made with LDH_5 isozyme

enzyme coenzyme complex[5-7]. If this is so the observations reported here allow the supposition that the coenzyme is bound more firmly to LDH_1 than to LDH_5, so protecting the tertiary structure of the enzyme molecule necessary to catalytic action.

The elevated pyruvate concentration increases the reaction velocity of urea-treated LDH_1. This consequently means that the affinity of the enzyme towards its substrate is lowered possibly as a result of changes in the conformation of enzyme molecule in its active centre caused by urea.

Preparation of Endotoxin

When a watery suspension of Gram-negative organisms is heated at 80° C for 1 h, the endotoxin is liberated into the suspending fluid, giving it a dichroic appearance; a method of preparing endotoxin on a large scale by recovering it from such a supernatant was described earlier[1]. In that method concentration was effected by evaporation under reduced pressure. This method, improved and modified to avoid this, is described here.

A culture is grown in a medium containing commercial-grade ammonium sulphate 0·5 g, glucose 1·0 g, disodium hydrogen phosphate 0·2 g, sodium citrate 0·2 g, and magnesium sulphate 0·02 g in 100 ml. of distilled water. A still culture in this medium with the *p*H held at 7·5 yields 3×10^9 and an aerated culture 10^{10} viable cells per ml. The cultures are stored at 4° C, and when there is a convenient quantity available they are centrifuged to obtain the cells in a stiff paste; the cells are re-suspended in distilled water to about 10^{11} cells/ml. and the suspension is heated at 80° C for 1 h and centrifuged. The cells are discarded and the oil-like supernatant is dialysed against running tap-water for 72 h to remove amino-acids, and the endotoxin precipitated in 75 per cent alcohol and dried. It is a slightly greyish sugar-like powder.

Greater purity can be achieved by (*a*) re-suspending the living cells in chilled water and repeating the centrifuging, (*b*) continuing the dialysis against distilled water, and (*c*) re-precipitating in 75 per cent alcohol.

In a typical batch the yield of endotoxin from 10^{15} cells of *E. coli* was 7 g and the LD_{50} of this by intraperitoneal injection in 18–22 g mice was 0·5–1·0 mg.

Depsides in Sunflower Leaves

This communication reports our finding of neochlorogenic, isochlorogenic, and 3-*O*-feruloylquinic acids in the leaves of sunflowers, *Helianthus annuus*, Russian Mammoth variety. The well-known chlorogenic acid (3-*O*-caffeoylquinic acid) has been previously found in sunflowers by Urban[1] and its presence there has been confirmed by Watanabe *et al.*[2].

Neochlorogenic acid, first isolated from peaches by Corse[3], has recently been proved to be 5-*O*-caffeoyl-D-quinic acid[4-6]. Isochlorogenic acid, as available commercially, has been shown to be a mixture of depsides[4-7]. Corse *et al.*[6] have identified one component as 4,5-dicaffeoyl-D-quinic acid, and Haslam *et al.*[5] have identified another component of the mixture as 3,5-dicaffeoyl-D-quinic acid. The isochlorogenic acid from sunflowers contains three components identical with three of the components, other than chlorogenic acid, of commercially available reference isochlorogenic acid. Neochlorogenic acid and isochlorogenic acid have previously been found in coffee beans, blueberry leaves, plums, and other fruits[8], but not in sunflowers. Recently, 3-*O*-feruloyl-D-quinic acid has been isolated as a crystalline material from unroasted coffee beans[9], but had not been found previously in sunflower plants.

Isolation and identification of neochlorogenic acid. Sunflower leaves (194 g) grown in the greenhouse of the Department of Botany, University of Oklahoma, were extracted by twice boiling the disintegrated leaves with 1 l. portions of 85 per cent isopropyl alcohol–water for 5 min. The extracts were filtered, concentrated *in vacuo* at 37° C to 250 ml. and extracted three times with benzene. The aqueous concentrate was poured on to a 4·5 × 10 cm chromatographic column which previously had been packed with 'Magnesol' (Food Machinery and Chemical Corp, N.Y.) and washed with distilled water under a pressure of 5 lb./in.^{2} pressure. The yellow zone on the column was developed with distilled water to produce two major zones, called fraction *A* and fraction *B*, which were eluted off separately. Fraction *A*, the faster moving zone, was streaked on to ten sheets of Whatman 3 *MM* paper and developed in *n*-butyl alcohol–acetic acid–water (6 : 1 : 2 v/v/v, here referred to as BAW). The broad zone at R_F 0·75 was cut out and eluted with methanol–water (1 : 1 v/v). The extracts were concentrated and streaked on ten sheets of paper and developed in butyl acetate–acetic acid–water (4 : 1 : 5 v/v/v) for 20 h. The broad zone at R_F 0·70 (chlorogenic acid) was separated from a narrow one at R_F 0·25. The latter zone was eluted and further purified by streaking the eluate on seven sheets of Whatman 3 *MM* paper and developing the chromatograms in BAW. This procedure was repeated on nine sheets of Whatman 3 *MM* paper, and then on eight sheets of Whatman No. 1 paper in isopropyl alcohol–formic acid–water (50 : 1 : 950 v/v/v, here referred to as IFW). The extract was taken to dryness *in vacuo*, dissolved in a small amount of methanol and poured on top of a 2·5 × 25 cm 'Magnesol' column previously packed under a pressure of 5 lb./in.^{2} with distilled methanol. The column was developed with one column length of methanol followed by methanol–water (1 : 1 v/v). The zone which fluoresced greenish blue under ultra-violet light (3660 Å) was collected. The absorption spectrum of the eluate showed a maximum at 326 mμ, shoulders at 242 and 300 mμ, and a minimum at 265 mμ. The eluate was taken to dryness and hydrolysed with 10 ml. of 5 per cent sodium hydroxide for 20 min at room temperature. The solution was then acidified with concentrated hydrochloric acid and extracted three times with ethyl acetate. The ethyl acetate extract was chromatographed on Whatman No. 1 paper to prove the presence of caffeic acid. After the evaporation of the aqueous phase, the dry crystalline residue was extracted with 5 ml. absolute ethyl alcohol. The alcohol extract on chromatography showed the presence of quinic acid. The hydrolysis products, the R_F values (Table 1), and the ultra-violet spectra on comparison with authentic neochlorogenic acid showed that the compound extracted was identical with the reference compound.

Isolation of isochlorogenic acid. Fraction *B*, the slower moving zone from the 'Magnesol' column, was concentrated *in vacuo* and streaked on 20 sheets of Whatman 3 *MM* paper and developed in IFW to give three zones. The broadest and most intense one under ultra-violet light at R_F 0·22 was cut out and eluted with 70 per cent isopropyl alcohol. The eluate was concentrated to a

low volume and extracted twice with ethyl acetate. The extracts were dried over anhydrous sodium sulphate and taken to dryness *in vacuo*. The absorption spectrum of an alcoholic extract of the residue showed maxima at 245 and 330 mμ, a shoulder at 300 mμ and a minimum at 265 mμ.

In all but one of the solvent systems used for paper chromatography (Table 1) the sunflower isochlorogenic acid produced only one zone on the chromatogram, and in each case this was identical with the isochlorogenic acid zone of the reference sample used. In 2 per cent acetic acid, however, the isochlorogenic acid from sunflower separated into zones with R_F values of 0·08, 0·16 and 0·30. The reference isochlorogenic acid (Fluka, Buchs *S.G.*, Switzerland) on the same chromatograms had R_F values of 0·09, 0·15 and 0·29, in addition to the chlorogenic acid zones.

Hydrolysis of the isolated acid was carried out by the procedure previously described for neochlorogenic acid. The R_F values of reference samples of quinic acid, quinide and caffeic acid were identical with the hydrolysis product zones in the solvent systems tried (Table 1).

Isolation of 3-O-feruloylquinic acid. Sunflower leaves (2,840 g) were extracted in a Waring blender with 10 l. of hot isopropyl alcohol. The extracts were filtered, concentrated *in vacuo* at 37° C to remove most of the organic solvent, and extracted three times with benzene to remove green pigments and lipids. The aqueous concentrate was then concentrated further to 140 ml. A column (3 cm diam.) was packed to a depth of 26 cm with 'Ultramidpulver' (Badische-Anilin und Soda-Fabrik, Ludwigshafen am Rhein) in distilled water under gravity, washed with dimethylformamide–acetic acid–water–ethyl alcohol (1 : 2 : 6 : 4, v/v/v/v) and then with water. The aqueous sunflower concentrate (50 ml.) was poured on the column and developed with distilled water. The yellow zone that was readily eluted off was concentrated *in vacuo* to 30 ml. and streaked on 110 sheets of Whatman No. 1 chromatography paper and developed in isobutyl methyl ketone–formic acid–water (14 : 3 : 2 v/v/v). The zone at R_F 0·60 which fluoresced faint blue under ultra-violet light (3660 Å) was cut out and eluted with 50 per cent methanol–water. The extract was re-chromatographed on fourteen sheets of Whatman No. 1 paper, and then on eight sheets in butyl alcohol–ethyl alcohol–water (20 : 5 : 11 v/v/v). The zone at R_F 0·74 was cut out and eluted with 50 per cent methanol–water. The ultra-violet absorption spectrum of the eluate showed a maximum at 323 mμ, a shoulder at 300 mμ, and a minimum at 263 mμ, the same as given by the authentic reference sample. Half this eluate was hydrolysed in the same manner as described for neochlorogenic acid to produce ferulic and quinic acids. The R_F values of the isolated depside and reference 3-*O*-feruloylquinic acid were identical in the solvent systems tested (Table 1).

This work was supported by a grant, *GB*–181, from the National Science Foundation. Dr. J. W. Corse supplied the authentic neochlorogenic acid, and Dr. E. Sondheimer supplied the reference 3-*O*-feruloylquinic acid.

Table 1. R_F VALUES OF ISOLATED AND REFERENCE COMPOUNDS

Compounds	Solvent systems* 1	2	3	4	5	6

PHYSIOLOGY

Metabolic Differences between Starch and Sucrose

SINCE 1957, papers from this department have stressed that the dietary factor involved in the aetiology of ischaemic heart disease is likely to be sugar (sucrose) rather than fat[1]. The evidence incriminating dietary sugar—now quite strong—is chiefly epidemiological. Investigations of populations show that the rise in the incidence of the disease coincides with the rise in the consumption of sugar and not of fat[2–4]. Again, during investigations of individuals we have shown that the disease is most likely to occur in those that have been eating a great deal of sugar[5].

Our suggestion that dietary sugar is a cause of ischaemic heart disease has sometimes been criticized on the grounds of implausibility (for example, Kinsell[6]). Sugar, we are told, is rapidly hydrolysed and rapidly absorbed as glucose and fructose, and the fructose is rapidly converted into glucose; in what way then can sugar act differently from the other major dietary carbohydrate, starch, which also rapidly appears in the blood as glucose? Are not all digestible carbohydrates interchangeable, so that they have identical metabolic effects?

In seeking for a possible mechanism by which sugar may induce ischaemic heart disease, we have therefore taken as our first task the discovery of differences in the metabolic effects of dietary sucrose and dietary starch. Our second task will be to see whether we can demonstrate which of these differences may be responsible for the involvement of sugar in the aetiology of heart disease.

A great deal of evidence contradicts the common belief that all forms of dietary carbohydrates are interchangeable. Macdonald[7], and Antar and Ohlson[8], have summarized some of the differences induced in man and in experimental animals when sugar is substituted for starch in the diet. The effects include an increase in serum cholesterol, changes in depot fats and liver fats, and diminished growth. In addition, Cohen and Teitelbaum[9] have found that sugar-fed rats exhibit an impaired glucose tolerance.

During the past year, we too have found several differences between starch-fed and sucrose-fed rats. We are now reporting these briefly with the purpose of combating the view that all dietary carbohydrates are equal, and particularly that starch and sugar are interchangeable.

All experiments were carried out on rats given purified diets and water *ad libitum*. The diets contained about 70 per cent carbohydrate, either as corn starch or as sucrose; except where noted, they were adequate in all known nutrients.

Diets containing sucrose produced a lower growth-rate in weanling rats (Fig. 1), or a loss of weight in adult rats, compared with diets containing starch. The effect was more noticeable when the diets were low in protein. The lower rate of growth was not due to a lower food intake, nor was there any difference in absorption. The effect must therefore have been due to less efficient utilization of the food.

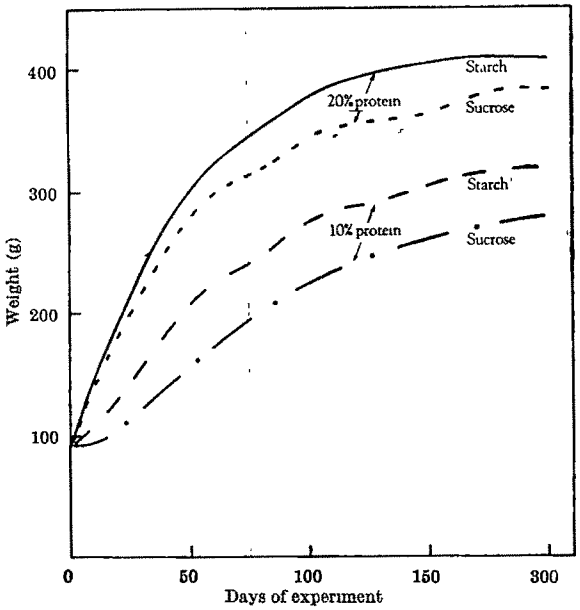

Fig. 1. Growth of male rats from the age of 28 days on purified diets containing two levels of protein, and 69 per cent carbohydrate in the form of starch or sugar. Each group consisted of four male rats

Measurements of oxygen uptake and carbon dioxide output were made in rats over periods of 24 h, about six months after they had been placed on the diets with starch or with sugar. The rats on the diet with starch gave the expected respiratory quotient of about 0·87. However, the rats on sucrose gave a respiratory quotient of about 0·75; this figure is far lower than that expected for a high carbohydrate diet, and similar to that expected (and, in fact, found) for animals on a high fat diet. We have at present no explanation for the low respiratory quotient of the rats on sucrose.

After feeding for six months, the level of serum cholesterol was higher in rats on the sugar-containing diet than in those on the starch-containing diet. The total body fat was significantly less in the sugar-fed rats. The liver fat was less in the sugar-fed rats when they were given the experimental diets from weaning; it was higher in the sugar-fed rats when they were given the diets from the age of three months (Table 1).

Table 1. Body Fat and Liver Fat in Rats fed Diets containing Two Levels of Protein, with 69 per cent Carbohydrate as Starch or as Sugar

Groups of four male rats fed on experimental diets for 6 months, from age 28 days (weaning) or age 3 months. Fat as percentage of dry weight of body or of liver

Young rats				Older rats			
Diet		Fat content		Diet		Fat content	
Carbohydrate	Protein	Body	Liver	Carbohydrate	Protein	Body	Liver
Starch	20%	35	12	Starch	10%	35	7
Sugar		30	9	Sugar		26	9
Starch	10%	32	9	Starch	5%	32	18
Sugar		32	7	Sugar		27	46

The major carbohydrate components of current human diets, especially in affluent countries, are starch and sugar (sucrose). Experiments have now shown conclusively that the substitution of one for the other in the diet of rats causes several metabolic changes. There is no justification for the view that starch and sugar are metabolically identical.

The effects of altering the carbohydrate in the diet stand in remarkable contrast to the effects of altering the fat in the diet. For example, Thomasson *et al.*[10] have given rats diets containing 54 per cent of the calories from fat, and compared natural soyabean oil with various hydrogenated soyabean and other oils. Some of these contained more than half of the fatty acids in the 'unnatural' *trans* form. They found no difference in body growth, body fat, kidney and liver function, and several other measurements.

Proton Transfer Processes in Muscle: Pressure, Temperature and Isotope Effects

Investigations of muscular contraction in heavy water have shown that the rate-determining process involves proton transfer[1]. The magnitude of the effect suggests that more than one proton is involved. Varga[2] has observed that fibres under isometric tension in the presence of adenosine triphosphate are relaxed when the temperature is lowered, an effect which has been attributed to the endothermicity of actomyosin formation. On the other hand, increasing the hydrostatic pressure results in contraction of intact muscle[3–5].

At 25° C the limiting equivalent conductivity of the proton is nearly ten times greater than that of the similarly charged and hydrated lithium ion[6]. This anomalously great mobility of the proton has been attributed to the Grotthuss mechanism[7,8]. This mechanism entails three steps: (1) the rotation of adjacent water molecules to form a transitory H-bonded chain; (2) proton flips along this chain; (3) dissolution of the chain and rotation of water molecules to return to a random distribution. Huckel[8] and Conway, Bockris, and Linton[9] maintain that one of the rotational steps is rate-determining, while Bernal and Fowler[10] and Stern and Eyring[11] believe that the proton flip is the slow step. Our more recent studies have shown that the rotational step is not only rate-determining, but also that protonic conduction by the Grotthuss mechanism is restricted to the 'free', rotatable, water monomers between the structured Frank-Wen clusters[12–14].

The Grotthuss conductive process avoids areas of order because the activation energy required to rotate a bound water (as in ice) is greater than that required to rotate a 'free' water molecule; 12 compared to about 3 kcal/mole (the latter at 10° C)[14,15].

Some time ago Klotz[16] proposed that certain long-range biological redox reactions might involve electron transfer via a Grotthuss-like mechanism. Studies of the Fe(II)—Fe(III) electron-exchange reaction in ice have substantiated such a possibility[17]. Thus the Grotthuss mechanism can sustain both transport of electrical energy by protonic conduction and transport of chemical energy by electron exchange[18].

Recent nuclear magnetic resonance investigations by Bratton, Hopkins, and Weinberg[19] have yielded evidence that in relaxed muscle fibre the solvation sheath water molecules are bound tightly to the protein material in an orderly manner, but that on contraction the waters are released and set 'free'. From this information Horne[20] drew the inference that the waters are released so that they can rotate and thereby transport electrical or chemical energy by the Grotthuss mechanism. The purpose of this communication is to examine whether the observed pressure, temperature and isotope effects support this hypothesis.

The application of either thermal energy or hydrostatic pressure tends to break up the structure of liquid water, the rotation of water molecules is facilitated, and, as a consequence, the activation energy of protonic conduction decreases. This is shown in Fig. 1 where the temperature dependence of the activation energy of electrical conduction of aqueous hydrochloric acid solutions, which is to say, the activation energy for water molecule rotation, is calculated from the results of Owen and Sweeton[21] and where the pressure dependence is from Horne, Myers, and Frysinger[12]. (It should be noted that the former is for molar, the latter for molal conductances.) Hydrostatic pressure also breaks up the local structure around ions in solution[22]; one expects by analogy that it also breaks up the local structure in the solvation sheath of biopolymers. If such is the case, then water rotation and the Grotthuss transport process is facilitated and pressure should be associated with muscular contraction, as observed[3-5]. By the converse of the same argument temperature reduction should be associated with muscular relaxation, as observed[2]. Notice that the endothermicity of actomyosin formation is not relevant unless that process is rate-determining.

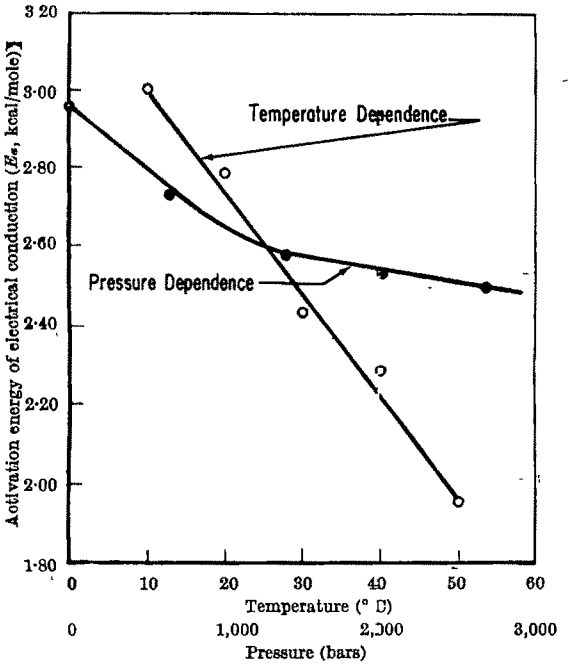

Fig. 1. Temperature and pressure dependence of the activation energy of electrical conduction of an aqueous 0·10 M hydrochloric acid solution

The isotope effect for electrical conduction by the Grotthuss mechanism is 1·1–3·0 (in water) or 2·2 (in ice) while that of electron exchange by the Grotthuss mechanism is 1·5–2·5 (ref. 18). The H_2O/D_2O effect for muscular contraction is about 3 (ref. 1). This value is commensurate with the values for the Grotthuss mechanism but may be slightly higher. Hydrophobic bonding plays a part in the hydration of biopolymers, unlike ions in solution or the bulk water structure. The disruption of such bonding involves the co-operative movement of more waters than does the disruption of electrostatic bonding, and this could easily give rise to a somewhat greater isotope effect.

Higher pressures, like higher temperatures, result in more profound and irreversible chemical reactions in proteins[23,24]. We visualize that at modest pressures (or temperatures) the waters of the biopolymer's solvation sheath are released and rendered 'free' to rotate in place. As pressure (or temperature) is further increased the sheath is totally disrupted and the water molecules may even stray away. The structured hydration sheath stiffens and stabilizes the biopolymers: when it is destroyed, both inter- and intra-molecular reactions occur resulting in denaturation and coagulation.

The bits of evidence discussed above all point to the conclusion that muscular contraction is associated with a release of the bound waters in the biopolymer's solvation sheath and with the transmission of electrical and/or chemical energy by the Grotthuss mechanism. However, the position of these processes in the temporal sequence of muscular contraction is far from clear. Are they cause or effect? In particular it would be most interesting to know the nature of the signal and of the processes in the protein which result in the release of its waters of hydration.

Fine Eye Movements during Inattention

Recording by numerous observers[1] during steady visual fixation has shown a highly typical pattern of fine eye movements (Fig. 1) invariably present, beyond voluntary control, and consisting of three components: rapid saccades (flicks); slow drift and waves; and fine fast tremor. While these movements are usually related to a control mechanism for keeping the eyes on target[2], some feel that they play a greater part in visual function[3], especially since an artificially stopped retinal image disappears to perception[4], and since there is an evoked occipital response correlated with saccadic movements[5].

An important question about visual function is: What is happening in the visual system when the subject is not

attending to vision? The question can be asked at a number of levels—introspectively, in psychological experiments, or in physiological experiments correlating electroencephalogram, electroretinogram, etc. This communication reports findings correlating types of fine eye movements with attention and inattention.

During routine experiments recording fine fixation eye movements by standard techniques it was discovered that when the mind of one subject wandered a new pattern of fine eye movement (Fig. 2) occurred. If the subject was afterwards instructed to attend to the task of fixation the eye movements would again revert to the normal pattern and the subject became retrospectively quite aware of his inattention. This happening occurred several dozen times, always identified by the changed characteristics of the eye movements, and the retrospective awareness of inattention, so that the relationship to inattention was invariable. These eye movements were oscillatory, without finite periods of steadily maintaining relative stability on a comparatively small area of the retina. such as is true of the ordinary movements.

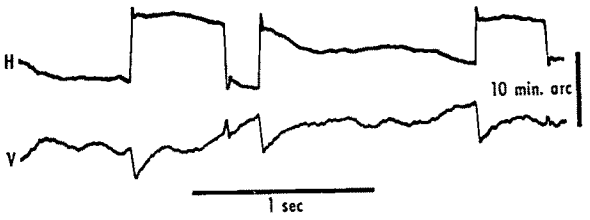

Fig. 1. Typical recording of fine eye movements with subject attending to task of fixating a small point. *H* is horizontal eye movement. *V* is vertical eye movement. Saccades, drift and slow waves and fine fast tremor can all be seen

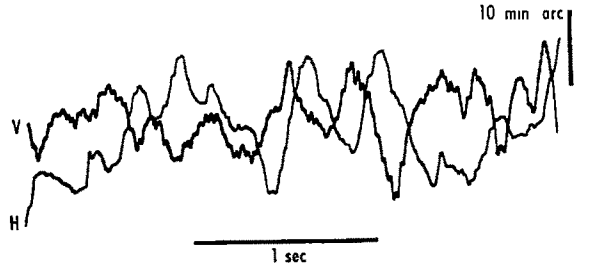

Fig. 2. Eye movements of the same subject during inattention several minutes later. *H* is horizontal eye movement *V* is vertical eye movement. Note infrequent saccades Note shifting phase relations of the traces, necessarily resulting in varying Lissajous figures describing the retinal image—retina relation over time

A feedback control system of fine eye movements might be assumed from this evidence to operate differently during attention and inattention. Most parsimoniously, it could be assumed that during attention there is a closed-loop feedback functioning with stability of the system, while during inattention the loop is opened, resulting in typical instability oscillation as recorded in artificially opened loops by Fender and Nye[2]. Thus, inattention would physiologically involve the opening of feedback loops which are ordinarily closed and operative. Although parsimonious, these assumptions should be tentative.

Another issue concerns the state of organization of visual information transmitted during attention and inattention. Introspection does not readily allow asking if what we see during inattention is different from during attention. The different space-time relationship of the retinal image to the retina during attention and inattention suggests that the organization of information transmitted by the optic nerve might be markedly different in the two states.

PHARMACOLOGY

Drosophila-tests in Pharmacology

In pharmacology the possible genetical effects of drugs have so far been neglected. One reason for this is that the test organisms used by pharmacologists are not convenient for genetical tests. A similar problem was faced by geneticists and developmental physiologists up to the 1930's. Through tests with *Drosophila*, *Neurospora* genetics was developed and later the whole branch of biochemical genetics.

The increasing use of drugs of various kinds might, in addition to secondary somatic effects, also cause genetic effects. Among these are included mutagenic effects of various kinds and effects on segregation of the chromosomes—non-disjunction. The latter will, in man, either cause the death of the foetus before birth, or might cause severe somatic and mental deficiency, for example, Down's syndrome.

For this reason it will be necessary to develop tests whereby drugs can be tested for such possible genetic effects.

The use of mammals—mice—in such tests would be both expensive and time-consuming, and might slow down even more the development of new drugs. Thus, compared with the normal time lapse in their introduction, the benefit of such tests could be small. It occurred to us that *Drosophila* might be used in such tests, as we there have the most refined genetical methods. The problem is whether or not we can conveniently observe any somatic effects which are dependent on dose.

This communication presents some experiments which show the possibilities of *Drosophila* tests.

As somatic effects I decided that developmental time and survival would be the best characters to observe. The normal developmental time for *Drosophila melanogaster* at the optimum temperature of 25° C is: egg stage slightly less than 1 day, larvae 4 days and pupae 4 days. In conditions that are not overcrowded the developmental time is thus approximately 9 days.

As the larval period is one of very active feeding I thought that the best method of introducing the drug was to allow newly hatched larvae to live on a medium in which it was mixed.

Normal *Drosophila* medium consists mainly of agar–agar, syrup, corn-meal and water. To such a medium were added various drugs which were then thoroughly mixed with the medium.

When various concentrations were to be tested I started with the highest concentration and to half of that added an equal amount of normal food and mixed it thoroughly. Half of this was then taken to obtain the next lower concentration, etc. The medium was poured into vials into which 25 newly hatched larvae were placed.

In order to obtain a great number of young larvae, flies were bred in plastic boxes in which there was a hole covered by a Petri dish containing a blackened medium of agar–agar, syrup and water. The Petri dish could be easily exchanged. Egg-laying was allowed for only 4 h. Twenty hours after the beginning of egg-laying the Petri dishes were inspected and larvae which had already hatched were discarded. Within the next 4 h the larvae were sampled in groups of 25 which were placed in the test vials. In order to get uniformity, 25 larvae were added to one vial from each concentration for each drug and their controls before the second vials were used. There was a total of 8–11 vials in each group. From the 8th day onward the vials were inspected and emptied every 4th or 6th hour, with the longer intervals at night. The number of adults ecloding in each period was recorded.

The developmental time was taken as the time from the mean of the egg-laying period until the time of inspection. For each concentration total mean developmental times for males and females were calculated. These are given in Figs. 1–3.

From these figures it is evident that in most cases there is a linear relationship between the concentration of the drugs in the medium and the time of development. For one drug there is a plateau and in two others seemingly no effects at all.

Table 1. ADULTS OUT OF 25 LARVAE PER VIAL

Conc.	*A*	*B*	*C*	*D*	Conc.	*E*	*F*	Conc.	*G*
4 g	17·5	22·9	23·5	17·1	2	18·3	19·2	1	21·8

1	19·2	22·0	22·5	23·7	1/2	22·4	19·6	1/4	22·6
1/2	21·4	23·7	22·0	23·2	1/4	22·4	20·0	1/8	23·1
1/4	22·6	22·0	23·2	21·8	1/8	21·5	21·4	1/16	23·5
Control	23 2	23 2	23·2	24·0		23·2	23 2		24·0

A, Pentothal sodium; *B*, hexobarbitone; *C*, *cyclo*barbitone; *D*, sodium-salicylate; *E*, phenobarbitone; *F*, diallylbarbituric acid; *G*, glutethemide.

As an example of the effects on survival I have used the same groups as presented in Figs. 1–3. The mean number of adults per vial with originally 25 young larvae are given in Table 1. It is obvious that there are some toxic effects at the higher concentrations of some drugs. The effects on survival are, however, not at all as distinct in relation to the concentrations as are the developmental times. In many cases there might be a correlation between the effects on development and survival.

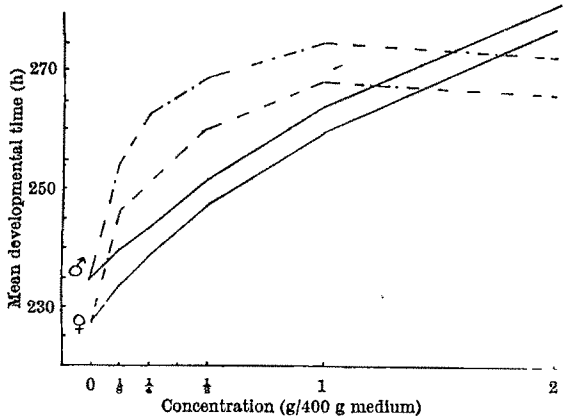

Fig. 1. —, Phenobarbitone; — · —, diallylbarbituric acid

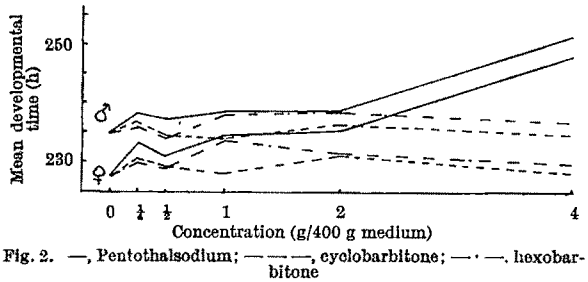

Fig. 2. —, Pentothalsodium; — — —, cyclobarbitone; — · —, hexobarbitone

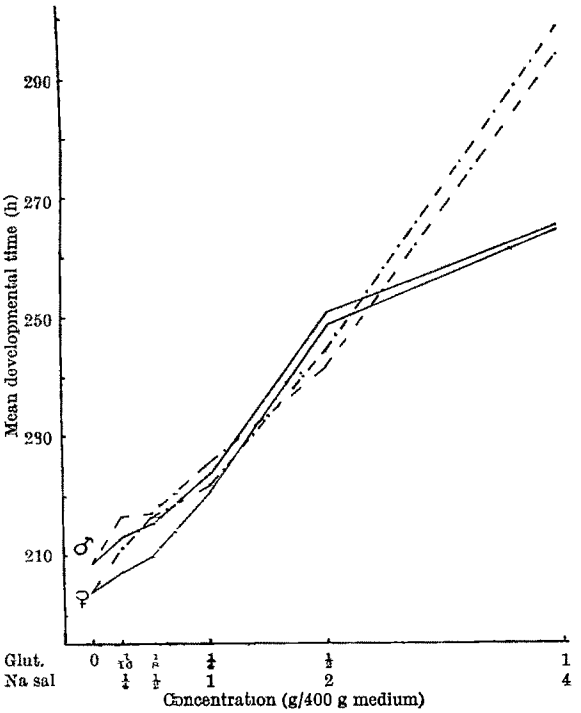

Fig. 3 —, Glutethemide; — · —, sodium salicylate

From these results we can conclude that lengthening of developmental time might be a fairly good indication of somatic effects. Furthermore, there is good evidence that individuals which have had a prolonged developmental time have been in one way or another affected by the drug, and thus may be used for further genetical tests.

In *Drosophila melanogaster* the first meiosis occurs in late larval stages of males, and during the pupal stage further cells pass meiosis.

Hence, possible effects of drugs could be manifested as chromosomal or genic disturbances in spermatozoa. We have chosen one of the drugs (glutethemide) used in the previous tests in order to see whether or not we could find any effects such as non-disjunction of the sex-chromosomes or chromosome breakage.

In order to perform such a test one needs stocks with convenient marker genes. The simplest method in this model test, namely, *y w sn* females and *y w sn* : sc^8Y males, was used. The males carry in their *Y* chromosome a very small piece from a normal *X*-chromosome with the wild-type allele of yellow. Thus the males are grey-brownish while the females have yellow bodies. If a female receives an extra *Y*-chromosome (*XXY*) they, too, will be grey-brownish, and if the males have but one sex-chromosome (*XO*) they will be yellow. By always using yellow-females and grey-brownish males one will be fairly certain that they are of the original normal types, *XX* and *XY* respectively. Non-disjunction will give *XXY* females which are phenotypically easily seen. The complementary class, *XO* males, may also result from other causes than non-disjunction, namely, chromosome lagging, or breaks resulting in the elimination of the broken chromosome. More *XO* offspring than *XXY* will therefore be expected. These types of aberrant individuals appear in normal stocks at low rates and for that reason one must run parallel controls on the experimental series.

In one preliminary test there was a significantly higher rate of non-disjunction in the glutethemide-fed group than in the control. It was then decided to perform two tests to confirm or refute this first observation. This time the material was divided into two groups according to the developmental time: the first half (early) and the second half of eclosions (late). The control group was bred at

room temperature (20° C) in order to cause a lengthening of developmental time for reasons other than drugs. The results of tests of males that had had their larval and pupal development on a medium containing 1 g glutethemide per 400 g (*D*), and the controls (*C*), are given in Table 2. As is seen, there is some variation but no clear trend. A comparison between the combined 4 glutethemide groups versus the controls gives no significant difference for any of the two types of aberrant individuals. We can therefore in this case conclude that the drug under consideration, although giving appreciable delay of development, has no detectable effects such as non-disjunction, lagging or breakage.

Table 2

Ser.	Total offspring	*XXY*	*XO*	10^{-4} *XXY*	10^{-4} *XO*
*D*1 *E*	47,144	25	117	5 3	24·8

D, glutethemide; *C*, control; *E*, the early half of eclosion; *L*, the late half.

These tests are presented in order to show the possibilities in using *Drosophila* techniques to detect agents with genetical effects. Although in this particular case we happened to test a drug which did not show any secondary effects on the chromosomes the method might prove successful with other drugs.

There might be objections to the use of an invertebrate in pharmacological tests since its physiology differs so much from man. It is true that we may in some cases have quite other types of effects in mammals, especially man. On the other hand, a potent agent might manifest its effect on an invertebrate as well as in mammals. Thus one could have some better ground for the detection of undesirable secondary effects on the genetic side rather than, as at present, continuing to neglect the problem by doing no studies at all.

Maintenance of Pregnancy in Spayed Rats with 20α-Hydroxypregn-4-ene-3-one and 20β-Hydroxypregn-4-ene-3-one

The two epimers 20α-hydroxy-pregn-4-ene-3-one (20α-progesterol) and 20β-hydroxy-pregn-4-ene-3-one (20β-progesterol) are in metabolic equilibrium with progesterone in ovaries[1–5], in the placenta[5,6], and probably in the adrenals[7]. They have also been isolated from ovarian and adrenal venous blood[3,8–13], their relative concentrations and their distribution varying from one species of animal to another[14]. 20α-Progesterol and 20β-progesterol possess certain progestational properties[5,15,16]. The purpose of the experiment described here was to determine to what extent and under what conditions the two epimers are able, like progesterone, to maintain pregnancy in the spayed rat.

Adult virgin female rats of the Sprague–Dawley strain weighing 200–250 g were placed in cages with adult male rats of the same strain on the evening of pro-oestrus. The following day, insemination was confirmed by the presence of spermatozoa in the vagina (1st day of pregnancy). The progestational steroids, in the form of a solution or a fine suspension in sesame oil, were administered subcutaneously twice daily (doses henceforth expressed in mg/kg daily) from the 8th to 19th day of pregnancy, either alone or in combination with oestradiol (1 μg/kg subcutaneously twice daily in sesame oil). On the 9th day, laparotomy was performed, pregnancy confirmed, and the animals (except for one group of intact controls) bilaterally ovariectomized. On the 20th day, all the animals were submitted to autopsy, during which the absence of ovaries was confirmed, the number of live and dead foetuses counted, and the two horns of the uterus examined for implantation sites.

Effect of the progestational compounds administered without oestradiol (Table 1). The two compounds 20α-progesterol and 20β-progesterol in doses up to 200 mg did not exert any pregnancy-maintaining effect. Progesterone, on the other hand, maintained pregnancy to some extent in a dose of only 12·5 mg. Following this dose, 33 per cent of the rats had 1–3 live foetuses; and the uteri of the rest of the animals either contained dead foetuses or showed implantation sites. A somewhat better effect was observed following 25 mg progesterone, while a dose of 50 mg maintained pregnancy in all the animals. In the latter case the number of live foetuses in the uterus was equivalent to that found in intact controls.

Effect of the progestational compounds administered together with oestradiol (Table 2). A partial response was elicited with 20α-progesterol. In response to a dose of 50 mg, a few dead foetuses were found in 25 per cent of the rats. With doses of 100 mg and 200 mg, foetuses—all of them dead—and implantation sites were found in 40–50 per cent of the animals.

Given in a dose of 50 mg, 20β-progesterol had only a limited effect: a few foetuses survived in 33 per cent of the rats, and dead foetuses were found in 22 per cent. A dose of 100 mg, on the other hand, resulted in complete maintenance of pregnancy, all animals containing a normal number of live foetuses.

Following a dose of only 3 mg progesterone, a certain number of foetuses survived in 66 per cent of the rats, and dead foetuses were found in all animals. The number of live foetuses found at autopsy in all animals treated with 6·25 mg, 12 mg, or 25 mg progesterone was comparable to that in intact controls.

Discussion. The finding that 20α-progesterol and 20β-progesterol show no ability to maintain pregnancy in the spayed rat when administered without oestrogen tallies with similar observations in the castrated mouse[17]. Under these conditions, the two epimers are less than 1/15 as active as progesterone.

Oestradiol, like oestrone in other experiments[18,19], reduced the dose of progesterone required to maintain pregnancy in the spayed rat to one-half or even one-quarter. Its synergistic effect appears to be even more marked with 20α-progesterol, and particularly with 20β-progesterol. The partial effect observed with 20α-progesterol probably indicates that maintenance of pregnancy was limited to a certain period of time after castration. When administered together with oestradiol, 20β-progesterol—in contrast to 20α-progesterol—produces qualitatively the same effects as progesterone, but is 15 times less active than progesterone.

The superiority of 20β-progesterol over its epimer is also apparent in the Hooker-Forbes test[5,16], in which it is twice as active as progesterone, whereas 20α-progesterone is two times less active. In the Clauberg test[5,16], by contrast, 20β-progesterol is 20 times less active than progesterone, whereas 20α-progesterol is only two times less active. The activity ratios between the two epimers and progesterone, as established in the course of these various tests, show that, in comparison with progesterone, 20β-progesterol and particularly 20α-progesterol have a weaker progestational effect on the maintenance of pregnancy than on the uterine mucosa. Hence, there is a marked dissociation between the various types of effect exerted by 20α-progesterol and 20β-progesterol. In order to explain this dissociation, it would be necessary to determine how

Excitatory Action of Prostaglandin E_1 on Brain-stem Neurones

PROSTAGLANDINS (PG) were first identified chemically in 1960 by Bergström and his co-workers[1–3] in extracts of sheep prostate gland, and since then they have been found in many other tissues. They are biologically active and stimulate or relax a variety of smooth muscle preparations[4]. Recently, evidence has been obtained for an action on the central nervous system following intraventricular or intravenous injection in small doses[5,6]. $PGF_{2\alpha}$ has been isolated from bovine brain[7] and evidence has been obtained that PGE_1 or PGE_2 is released from the cerebral cortex into a superfusate following afferent or cortical stimulation[8]. Krnjević, however, was unable to detect any action of PGE_1 on cerebral cortical neurones when it was released by iontophoresis[9].

Since some of the effects observed following the intraventricular or intravenous injection of prostaglandins[5,6] might have been due to an action on the brain-stem, it was decided to test for an action of PGE_1 on neurones in this region. A sample of PGE_1 (95 per cent purity) was supplied by Dr. D. A. van Dorp and initially a solution of 1 mg in 0·2 ml. adjusted to *p*H 8·2 with sodium hydroxide was used. In later experiments, this concentration was doubled and the *p*H was 6·7. The PGE_1 solution was placed in one barrel of three-, four-, or five-barrelled micropipettes. These were inserted into the medulla of unanaesthetized decerebrate cats and the spontaneous activity of single neurones was observed before, during and after the iontophoretic application of PGE_1. The methods used have been described elsewhere[10–12]. Histological controls showed that most of the neurones studied were in the medial reticular formation of the medulla.

Out of 265 neurones studied, 75 (28 per cent) were excited and 184 (70 per cent) were unaffected by PGE_1. The active ions were expelled from the electrode by a negative current and an equivalent current was passed through a saline-containing barrel as a control. A negative current through the control barrel sometimes caused excitation, but an effect of PGE_1 could be distinguished by a comparison of the magnitude and time course of the two effects, or by adjusting the current strength until it had no action when applied via the saline barrel. With some neurones, repeated application of PGE_1 led to a progressive reduction in effect whereas with others its magnitude remained relatively unchanged. The effects observed could not have been due to the expulsion of hydroxyl ions since the activity of PGE_1 was the same at both *p*H 6·7 and 8·2.

In some experiments, the effects of two related substances were compared with those of PGE_1. Approximately half the neurones excited by PGE_1 were similarly affected by the precursor, homo-γ-linolenic acid[13]. On the other neurones, it had only a slight effect or no effect at all. Linolenic acid was also active on some of the neurones excited by PGE_1 but inactive on others.

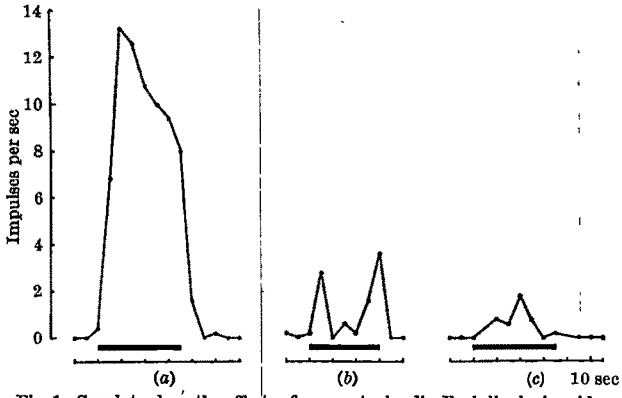

Fig. 1. Graph to show the effects of: *a*, prostaglandin E_1; *b*, linolenic acid; *c*, current, each applied with a current of 100n amp, on the impulse frequency of a medullary neurone

The excitatory action of PGE_1 on a neurone in the medial reticular formation of the medulla is shown in Fig. 1. At rest, this neurone fired only occasionally, but it was markedly excited by PGE_1, while current and linolenic acid had relatively slight effects.

Thus PGE_1 not only has an action on the central nervous sytem when injected intraventricularly or intravenously in very small quantities, but also has a selective excitatory action on brain-stem neurones. Since a related substance (PGF_{2a}) has been found in brain, the possibility that one of the prostaglandins or a related substance has some function of biological importance in relation to neuronal activity must be considered.

Liver Metabolism of Anticholinesterase Compounds in Live Rats: Relation to Toxicity

The insecticide 'Isolan' (1-isopropyl-3-methyl-5-pyrazolyl dimethylcarbamate) is more toxic to rats by the dermal than by the oral route[1]. This finding is interesting, because the opposite is true of most compounds. It was not known whether the unexpected difference in the toxicity of 'Isolan' by the two routes was caused by detoxification in the intestinal lumen, poor absorption from the gastrointestinal tract, detoxification in the liver, unusually efficient percutaneous absorption, or some other mechanism.

It is generally recognized that the liver is the main site of metabolism of foreign compounds in mammals.

Compounds may enter the body through a variety of routes: the gastrointestinal tract, skin and respiratory system being the most important. Absorption by any of these routes involves either the lymph or the blood as a primary transport medium. The lymphatic circulation and the capillary blood networks of the skin and lung discharge into the systemic blood circulation; the blood is then passed through the heart and on throughout the body. The liver receives about 6·5 per cent of the cardiac output directly through the hepatic artery and another 21 per cent of the cardiac output less directly by way of the mesenteric arteries and portal venous circulation. In contrast, the blood capillary network of the gastrointestinal tract discharges directly into the liver via the hepatic portal venous system, and essentially 100 per cent of this blood is delivered into the liver. Thus (if one ignores the possibility of a compound being sequestered by a given tissue or capillary bed) virtually all of a compound absorbed by the gastrointestinal tract goes directly to the liver; whereas, if a compound is absorbed from any other site, only 27·5 per cent reaches the liver before being distributed in the general circulation.

To test the effect of a single pass through the liver, 'Isolan' was injected directly into the hepatic portal system (intestinal vein) in one group of rats and into the general circulation (femoral vein) in another group. Similar investigations were conducted with two organic phosphorus compounds—dichlorvos, a direct inhibitor of cholinesterase, and parathion, an indirect inhibitor. It is well known that parathion is converted to the highly toxic paraoxon in the liver, but it is presumably in the liver also that it is eventually detoxified.

Adult female Sherman strain rats were paired according to age and body-weight and prepared for infusion by cannulating the intestinal vein of one rat and the femoral vein of the other. Surgery for installation of the cannulae was performed on the rats while under anaesthesia with methohexital sodium solution given by intraperitoneal injection at a dosage level of 80 mg/kg. The method of cannulation of both veins was the same as that described by Ross and Rappaport[2] for cannulation of mesenteric veins.

As soon as the cannulation was completed and the incision sutured, each rat was confined to an individual restraining cage[3]. The cannulae were each fitted over the tip of a 27-gauge hypodermic needle and attached to separate 5-ml. hypodermic syringes on a dual infusion pump. Each rat was infused with normal saline, at the same rate as the poison formulation was later infused, for at least 1 h or until both rats recovered from the anaesthesia if recovery took longer. Then the syringes of normal saline were replaced with syringes containing the poison, and the infusion of the poison was started simultaneously in both rats.

Preliminary investigations were conducted with each of the compounds in a deliberate effort to establish a concentration, infusion rate, and duration of infusion which would kill all the rats infused by one route and allow those infused by the other route to survive. Once

these conditions were determined for a compound, all the rats infused with that compound were infused at the same concentration and rate and for the pre-determined period of time, unless they died earlier. Based on the results of the preliminary tests, the compounds (all technical grade) used in this investigation were formulated and infused as shown in Table 1.

Each rat was observed continuously during the infusion of poison, and a complete record kept of time of the onset and course of symptoms and of the time of death. Except for the earlier detection of facial muscle fasciculation in some of the rats, the first symptom of poisoning was light generalized muscle fasciculation. Consequently, the time of onset of the latter was indicated as the time of onset of symptoms. Rats which survived the infusion were held for observation until recovery from symptoms, but not necessarily until recovery from cholinesterase inhibition.

The toxicity of 'Isolan', dichlorvos, and parathion infused into the hepatic portal system (intestinal vein) compared with their toxicity when infused directly into the general circulation (femoral vein) in rats is shown in Table 2. Based on time to onset of symptoms, time to death, and mortality in the poisoned rats, it is apparent that 'Isolan' and dichlorvos infused into the hepatic portal system undergo considerable detoxification during a single passage through the liver before they reach the general circulation. On the other hand, parathion infused into the hepatic portal system is more toxic than when infused by way of the femoral vein into the general circulation.

Time to onset of symptoms caused by 'Isolan' and dichlorvos was delayed about three times as long in rats infused into an intestinal vein as in those infused in the femoral vein. Six rats given a mean total dose of 0·73 mg/kg of 'Isolan' in the femoral vein were killed, but 5 of 6 rats given a mean total dose of 1·63 mg/kg by intestinal vein survived. A mean total dose of 5 0 mg/kg of dichlorvos killed 6 rats infused in the femoral vein, but 6 rats infused in an intestinal vein survived a mean total dose of 15·2 mg/kg.

The results for parathion presented in Table 2 indicate that the time to onset of symptoms in rats infused in the femoral vein was about twice as long as that for rats infused in an intestinal vein. However, 3 of the 6 rats infused in the femoral vein for 75 min never exhibited any signs of poisoning and none of the 6 rats died. All the 6 rats infused in an intestinal vein were killed in 57–75 min.

It is clear that efficient detoxification of 'Isolan' by the liver *in vivo* is one factor contributing to its relatively low toxicity by the oral as compared to the dermal route. However, one or more other factors must be important, for the detoxification of dichlorvos by the liver seems equally efficient, and yet dichlorvos is slightly more toxic by the oral than by the dermal route. Even though other techniques will have to be used to explain fully the pattern of toxicity of 'Isolan' when given by different routes, the technique presented in this report is a useful and relatively simple procedure for learning the net effect of the liver on the metabolism of chemicals in intact laboratory animals.

Table 1. Formulation of Compounds and Rate of Intravenous Infusion in Female Rats

Compound	Vehicle	Formulation Concentration of poison (mg/ml.)	Infusion rate (ml./rat/min)	Maximal period of infusion (min)
'Isolan'	Normal saline	1·0	0·0083	60
Dichlorvos	Modified 'Lipomul'*	12·5	0·0068	60
Parathion	Modified 'Lipomul'*	1·0	0·0068	75

Incompatibility of Synthetic Tetraicosapeptide Corticotrophin with the Present U.S.P. and International Corticotrophin Standard

Corticotrophin, unlike insulin or the octapeptides of the posterior lobe of the pituitary gland, is known to exist in different biological forms, due to inconsistencies in bioassays in which various routes of administration are used. The first hormone preparations used were of the same type as the first and second International Standard, that is, crude corticotrophin—a glacial acetic acid extract of pituitary glands. When in 1951 the oxycellulose adsorption method of Astwood *et al.*[1] yielded a highly purified hormone, the bioassays carried out by subcutaneous injections into hypophysectomized rats showed, on the average, potency estimates three times greater than the classical assay method (Sayers test) which involves intravenous injection. This phenomenon led to a type distinction of oxycel-purified ACTH from crude corticotrophin, the former being called corticotrophin *A* (Wolfson[2]). Another attempt to purify corticotrophin involving peptic or strongly acid hydrolysis yielded preparations of lower molecular size (about 28 amino-acid residues), which also differed biologically from crude corticotrophin[3]. In this case the ratio of potencies observed after subcutaneous and intravenous comparison with the latter was reversed and of the order of 1 : 4. This third biological ACTH type was designated corticotrophin *B* or actide (ref. 2). The foregoing ratios were obtained in rats but appear, in the main, to agree with those in man so far as crude corticotrophin and corticotrophin *A* are concerned. Bearing in mind that ACTH is mainly given subcutaneously (extravascularly), corticotrophin *A* may be regarded as the most important type of native ACTH due to its high degree of purity and

	19.3.65	16	183·9	2·4146	260	
	Total	64	409·1	Weighted mean 2·4088	256·4	204–322

favourable efficiency when given extravascularly. It is partly for these reasons that the now official International and U.S.P. Corticotrophin Standard preparations are of the corticotrophin *A* type, a fact which has practically eliminated bioassay discrepancies (crude corticotrophin is now rarely used). The reasons for the foregoing bioassay discrepancies are unknown, but it is most likely that they lie in the different rates of inactivation of the different types of ACTH at the site of extravascular administration.

The recent introduction of synthetic corticotrophin (tetraicosapeptide-Ciba), which due to its lower molecular weight should belong to the corticotrophin *B* type, has created a new situation, since formerly this type was not in general use. We tested the hypothesis of a type-difference between the synthetic tetraicosapeptide and the International Standard for corticotrophin (corticotrophin *A*) by a method utilizing the increase in the corticosteroid-level of mouse plasma. This method, devised by Rerup and Hedner[4], has been shown to give valid potency estimates for corticotrophin *A* preparations. Typical results are shown in Table 1.

It will be noted that the synthetic tetraicosapeptide when given subcutaneously showed only about 13 per cent of the activity expected from the assay using intravenous injection. Thus there can be no doubt concerning the strong biological difference between the present (International and U.S.P.) standard and the synthetic peptide. From this it follows that, so long as the international unit is used as a reference for corticotrophic activity, labelling of the synthetic product in weight units (mg) is inappropriate, since there does not appear to exist a fixed constant of equivalency of weight unit to biological unit. The findings indicate the need for (*a*) a clear distinction between preparations for intravenous and subcutaneous use (U.S.P. 1955)[5]; (*b*) a parallel study in man and laboratory animals to assess the equivalent of 1 mg of the tetraicosapeptide in international units after both intravenous and subcutaneous injections.

PATHOLOGY

Carcinoma of the Glandular Stomach in Rats given Diets containing Aflatoxin

Spontaneously occurring carcinoma of the glandular stomach in the rat is exceedingly rare. In a large series Bullock and Curtis[1] reported a single case, while Stewart *et al.*[2] in a review of the literature failed to find a convincing example of adenocarcinoma of the stomach in the rat. Experimentally, Hare *et al.*[3] produced a low incidence of glandular carcinoma on intramural injection of the carcinogenic polycyclic hydrocarbons. The same substances on feeding failed to induce carcinoma of the stomach. Stewart *et al.*[2] have since demonstrated that oral administration of *N,N'* 2,7-fluorenylene*bis*acetamide will induce a low incidence of stomach adenocarcinoma (4 in 47 rats), and Schoental[4] has reported the induction of malignant adenocarcinoma with *N*-nitroso-*N*-methylurethane (NMU). It is the purpose of this communication to describe the incidence of carcinoma of the glandular stomach observed in a series of experiments in which the toxicity of groundnut meal containing aflatoxin was investigated.

In our original experiments to examine the toxicity of groundnut meal we reported two definite adenocarcinomas of the stomach while a third animal had multiple metastases from a histologically similar adenocarcinoma. These experiments were started when the rats were about 5 weeks old and the animals were killed 66–76 weeks after the start of the experiment[5].

In further experiments rats have been given a diet made up with 50 per cent of the same batch of groundnut meal. The level of aflatoxin in the diet was 3–4 p.p.m. In one experiment 6 male rats 1 year old were given the diet to test its effects on old rats. Five of the 6 rats survived for more than 39 weeks, the sixth dying of middle-ear disease after only 9 weeks on the diet. Of these animals 3 showed anaplastic hepatocellular carcinomas. Two of these animals also had a further primary carcinoma, one an adenocarcinoma of the rectum and the other an adenocarcinoma of the stomach. The rat with the stomach carcinoma was 104 weeks old. In other experiments to be reported in detail elsewhere, the effects of short-term administration of aflatoxin were investigated.

Six young rats were given the diet for 3 weeks and then returned to a normal diet; one animal which lived for 106 weeks after return to the normal diet developed a carcino-sarcoma of the stomach. In this group of 6 animals only one developed a hepatic carcinoma.

Thus a total of four confirmed and one probable carcinoma of the glandular stomach have been seen in rats fed aflatoxin. Although the overall incidence is low, the tumours reported here are of considerable interest in view of the difficulty with which this type of carcinoma can be induced.

It has been suggested that aflatoxin may play a major part in the aetiology of human liver carcinoma in some parts of the world[6]. Carcinoma of the glandular stomach also shows an interesting geographical distribution, and it is possible that this type of food contaminant may be a factor in the aetiology of carcinomas in organs other than the liver.

Experimental Pyelonephritis in the Rhesus Monkey

Experimental work on pyelonephritis has been confined to rabbits, rats and mice[1]. The investigation on rhesus monkeys recorded here was undertaken because this species is phylogenetically close to man and, therefore, has better chances of developing the various characteristics of the human disease rather than any other labora-

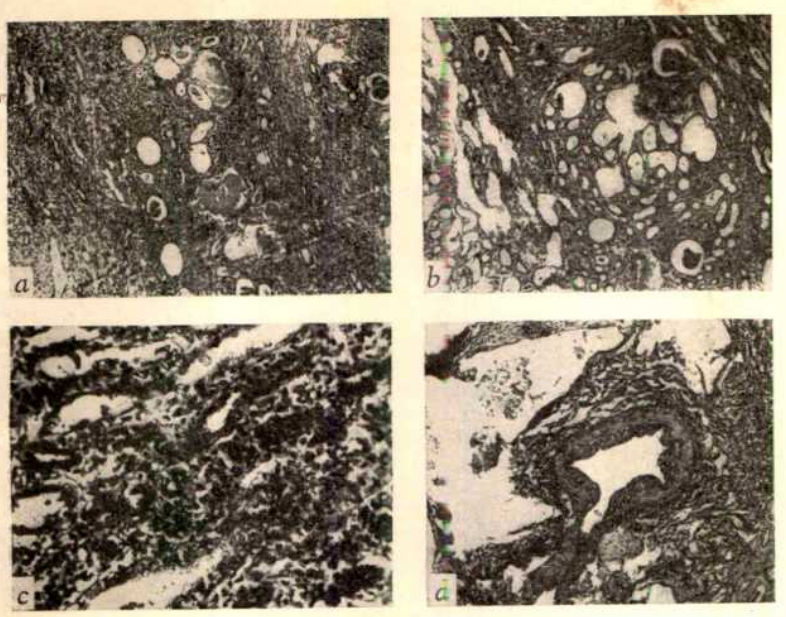

Fig. 1. *a*, Section of left kidney showing diffuse infiltration of interstitial tissue with inflammatory cells, destruction of renal tubules, casts in dilated and cystic tubules and shrunken glomeruli as a result of chronic pyelonephritis (× *c*. 70). *b*, Section of left kidney showing markedly dilated and cystic tubules with atrophic epithelial lining along with diffuse cellular infiltration of interstitial tissue (chronic pyelonephritis) (× *c*. 70). *c*, Section of left kidney showing destruction of renal tubules and interstitial cellular infiltration with mononuclear histiocytes, plasma cells and lymphocytes (× *c*. 250). *d*, Section of the pyelonephritic left kidney showing intimal elastosis of a medium-sized interlobar artery (× c. 70). Figs. *a–c*, haematoxylin and eosin; Fig. *d*, Verheeffs' stain

tory animal. This preliminary communication describes the techniques employed for the production of chronic pyelonephritis.

Twelve healthy animals weighing 2–2·5 kg were caged individually and were given a diet made up of soaked grain, green vegetables and bread. After adapting them to the laboratory conditions for a fortnight they were subjected to laparotomy aseptically under sodium pentothal anaesthesia. The left ureter was exposed and partially ligated by silk thread 2 cm below the hilum of the kidney, thus producing hydronephrosis. The right kidney served as control. 15 days after this operation, two doses of 18-h broth culture of haemolytic and coagulase positive *Staphylococcus pyogenes* representing $9{\cdot}76 \times 10^8$ organisms per ml. were injected into the femoral vein at a week's interval. The optimum dose of the culture which was found to avoid mortality was 0·5 ml. initially followed by 1 ml. after a week.

The animals were killed after 8 weeks of the second injection and autopsy performed. Culture of heart blood, liver, spleen, both kidneys and of urine was performed. The tissues were examined grossly and blocks fixed in 10 per cent neutral formaldehyde saline for histopathological studies. Paraffin sections 5μ thick were cut and stained with haematoxylin and eosin. Special histochemical techniques were used whenever required.

Although they became thinner, the test animals kept well throughout the experiment. Bacteriological examination of specimens at autopsy yielded growth of *Staphylococcus pyogenes* from the left kidneys of two animals which resembled the original culture morphologically and biochemically. The tissues of the remaining animals were found to be sterile.

The left kidneys were enlarged and showed hydroureter and hydronephrosis. The renal calyces were ill-defined, and the pelvic surface was shaggy. In one animal, the left kidney was markedly shrunken and the cut surface showed fibrous bands running irregularly in the renal parenchyma. The right kidney showed congestion. The urinary bladder was unaffected.

The microscopic examination of the left kidney showed inflammation and degeneration of tubular epithelium and cystic dilatation with protein and leucocyte casts. In the interstitial tissue oedema and capillary dilatation with diffuse infiltration by mononuclear histiocytes, lymphocytes, plasma cells and occasional polymorphs were seen. Early fibrous proliferation was also noted. The glomeruli appeared normal. Some of the renal arterial branches had fibro-elastic intimal thickening (Fig. 1*a–d*). The pelvic epithelium showed atrophy and the sub-epithelial zone was markedly inflamed. Examination of the right kidney showed a normal appearance in all the animals except two, in which interstitial inflammation with slight tubular degeneration were noted.

The tissues of the control group of monkeys did not show any pathological process.

The work recorded here has provided for the first time new information regarding suitability of rhesus monkeys for research on pyelonephritis. The morbid changes observed had many features of the human disease, for example, isolation of causative organisms from the kidney, presence of internal hydronephrosis, diffuse interstitial nephritis and vascular changes. It was also found that kidneys are particularly prone to localization of the pathogenic organisms if obstruction to urine flow is achieved. In other laboratory animals also, this point has been emphasized[2–5]. In this work, however, no advanced pictures of pyelonephritis or scarring of kidneys or inflammatory changes of urinary bladder were detected. This could have been due to the short period of observation.

We thank Dr. Mohini Malhotra for her help in standardizing surgical techniques in this experiment.

Is there a Cortex–Medullary Cord Barrier in Lymph Nodes?

This communication discusses the evidence for a barrier between the cortex and the medullary cord of rat lymph nodes, as suggested by the regional distribution of lymph-borne particulates within such a node, and also by the cytological pattern of its reaction to intense antigen stimulation.

A useful method of examining particle distribution is to inject 0·1 ml. of iron–dextran ('Imferon', Benger) into the right hind footpad of the 80–100-g rat. 3-μ paraffin sections stained by Prussian blue are then used to plot the distribution of iron-marked macrophages in the medullary structures of the corresponding para-aortic lymph node, at graduated time intervals after this footpad injection.

From 0·5 to 24 h afterwards, medullary sinus macrophages are heavily outlined, but little iron is found in the cords. After 24 h, iron-marked macrophages in cord and sinus regions can be easily observed. After 2 days, relatively less iron is found in the sinuses; but in the cords closely packed groups of macrophages are seen to be laden with Prussian blue-positive material. Adjacent to this

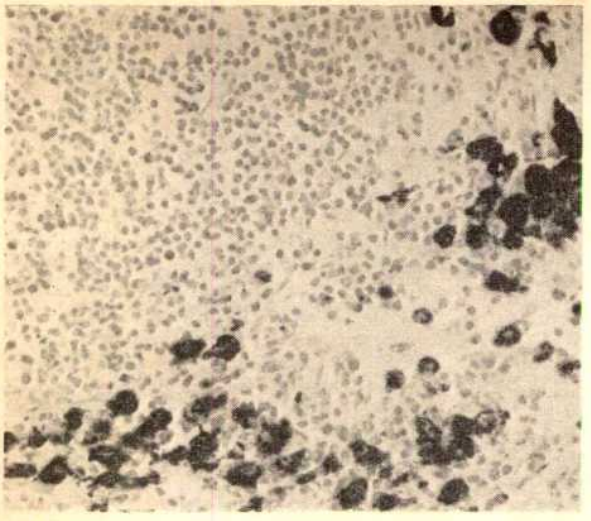

Fig. 1. View of cortex, top left, and medulla, bottom right, of para-aortic lymph node of rat 4 days after one footpad injection of iron-dextran. The maximum concentration of iron-marked macrophages is in the medullary cords. The cortex contains no visible iron. In terms of marked macrophages, there is a sharp cortico-medullary transition. Formol-fixed paraffin sections cut at 3μ, stained by Prussian blue-nuclear fast red (× *c.* 95)

heavy cord marking, the macrophages of the inner cortex contain little or no iron (Fig. 1). Especially in 4-day preparations, this gradient can be very abrupt.

Para-aortic lymph nodes have been observed for up to 9 weeks after a footpad iron–dextran injection. At the end of this time, some scattered cortical macrophages have become Prussian blue positive. However, the general exclusion of iron from the inner cortex remains unchanged. These regional peculiarities of macrophage iron–dextran distribution are duplicated by lymph-borne carbon used under similar conditions ('Pelikan' indian ink, Gunther-Wagner, *C*11/1431*a*).

The behaviour of lymph-borne particles thus suggests a barrier between the medullary cord and the cortex, in spite of the fact that collagen and reticulin stains do not support such a suggestion, nor does the adherent carbon-frozen section technique, as described in a previous communication[1], show any obvious organization of macrophage processes at this site (Fig. 2).

Yet certain cytological observations support a cortico-medullary barrier concept. Antigen stimulation by TAB vaccine (0·1 c.c. Commonwealth Serum Laboratories vaccine twice daily for 5 days) produces a sequence of blast-plasma cell change in the medullary cords, while the adjacent cortex shows remarkably little alteration of its predominantly small lymphocyte population. The line of separation between the lymphocytes of the cortex and the blast-plasma cell population of the adjacent medullary cord can be visually abrupt on the low-power view (Fig. 3) although higher magnification usually shows a zone of transition rather than a sharp boundary line.

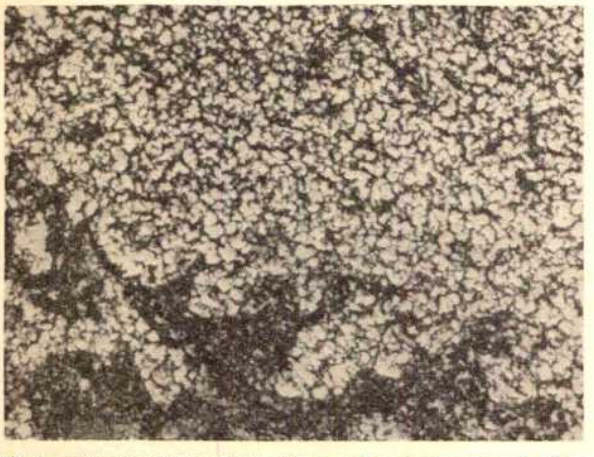

Fig. 2. View of cortex, top right, with macrophage processes marked by adherent carbon. Bottom left, the medullary sinuses are dark because of their dense macrophage concentration. Between the sinuses, the medullary cords can be seen in the region of the cortico-medullary junction. There is no special macrophage organization in this zone to suggest a cortico-medullary barrier. 10-μ frozen section, unfixed. Stained by adherent indian ink (× *c.* 130)

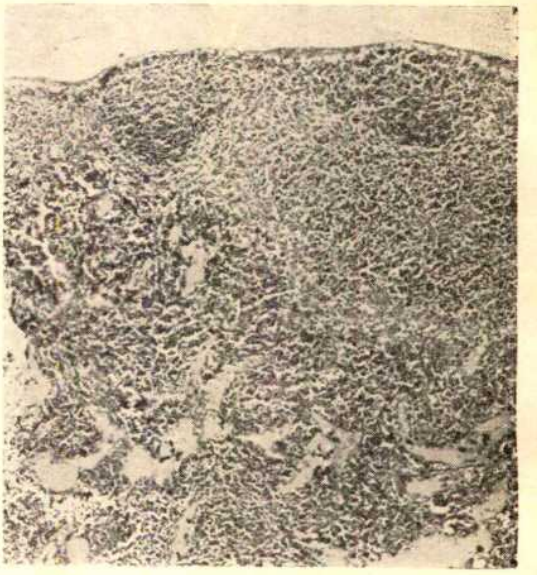

Fig. 3. View of cortex, top right, with medullary cords and sinuses, bottom left, at the end of a TAB antigen course by footpad injection, as described in text. The cortex maintains its small lymphocyte population; the medullary cords are full of maturing plasma cells. Visually, these two populations show an abrupt cortico-medullary transition. Formol-fixed paraffin sections cut at 3μ, stained by haemalum (× 50)

Electron microscopic observations will be necessary to confirm objectively the presence of this cortico-medullary barrier, which has so far been inferred only by indirect means. Further investigation into this point is now in progress.

RADIOBIOLOGY

Radiation-induced Mitotic Delay in Spermatogenesis of *Drosophila melanogaster*

Welshons and Russell[1] demonstrated in their histological observations on the testis of X-irradiated adult *Drosophila* males that secondary spermatogonia and young primary spermatocytes are easily killed by X-rays and that their destruction results in a period of temporary sterility of the males. These data were tabulated by the authors in a semi-quantitative way. If one presents the results graphically (Fig. 1) it becomes evident that, besides cell killing, mitotic delay has been induced by the exposure to X-rays.

The authors find that the minimum of curve *A* at day 2 is caused by radiation-induced degeneration of secondary spermatogonia and young primary spermatocytes. The minimum of curve *B* is explained by assuming that the old primary spermatocytes develop into sperm without degeneration and without being immediately replaced from the spermatogonia. However, the minimum of curve *B* is lower than that of *A* and—after curve *B* has gone through this minimum—the frequency of *B*-cells temporarily exceeds the control value. These two facts can easily be explained by postulating mitotic delay of at least a part of the *A*-cells. If these *A*-cells

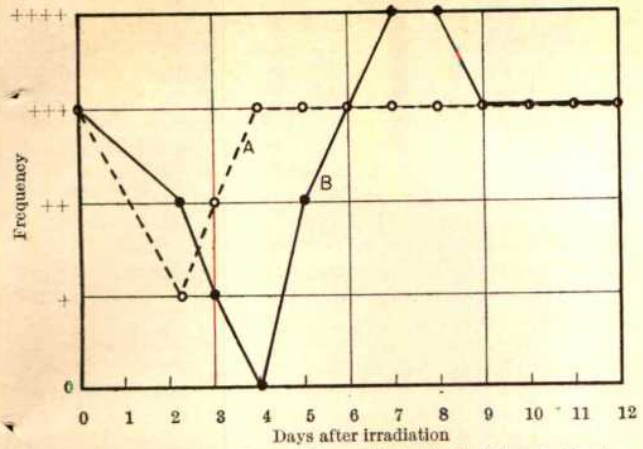

Fig. 1. Histological condition of *Drosophila* testis of adult males irradiated with 4,000r X-rays (after ref. 1). The normal condition of the testis is designated by + + +, conditions characterized by radiation induced decrease of the number of germ cells are designated by + +, + and 0. *A*, Secondary spermatogonia and young primary spermatocytes; *B*, old primary spermatocytes

interrupted their development the minimum of curve *B* might become lower, as if it were determined only by the frequency of killed *A*-cells. When the younger *A*-cells, which were not delayed in their development, together with the delayed *A*-cells, formed *B*-cells, the frequency of *B*-cells was raised above its normal value by this process of synchronization. One wonders why there is no corresponding excess of *A*-cells; perhaps this increase was not detectable by this semi-quantitative investigation.

Though the authors do not discuss mitotic delay in their paper, we feel that their observations do support the postulate that radiation-induced mitotic delay occurs in the testis of *Drosophila melanogaster*. If so, mitotic delay, as well as cell killing and dominant lethality, contributes to the sterile interval observed in brood pattern experiments utilizing irradiated *Drosophila* males.

I thank Prof. D. W. Dittrich and Dr. S. Bhaskaran (Münster) and Dr. W. J. Welshons (Oak Ridge) for their advice.

Note added in proof. The symbols *A* and *B* used in this communication have nothing to do with the classification of mouse spermatogonia into type *A*- and *B*-cells.

BIOLOGY

Root Cap and the Perception of Gravity

During investigations into the fine structure of apical meristems under the electron microscope, one of us (S. G.) discovered that it was possible, in maize and barley, to detach the intact root cap cleanly from the rest of the root tip. This is shown in Fig. 1. The roots of grasses are characterized by having a discrete cap meristem and, as can be seen in Fig. 2, a very well marked boundary between the cap and the root proper. The fracture takes place through the unstrengthened walls of the meristematic region of the cap as indicated in Fig. 2. We have not so far succeeded in removing the cap intact from other species such as broad bean or pea.

Removal of the cap has no effect whatever on the growth in length of the root as a whole, whatever the orientation of the root may be. This is in strong contrast to the early claims[1], on which much of the theory of root growth control has been based, that decapitation accelerates extension rate. On the other hand, removal of the root cap (which we shall henceforth call decapping) completely prevents the perception of the gravitational stimulus, and decapped roots will continue to grow horizontally for up to 30 h without check or curvature.

Regeneration of the root cap follows decapping and is complete at 28° C in about 36 h. An increase in temperature accelerates the regeneration and we have some evidence that young roots replace their root caps more rapidly than do older roots. The quiescent centre[2] of the root is exposed on its distal margin by the removal of the cap, and it is the cells of the quiescent centre, stimulated into rapid meristematic activity, which replace the cap meristem and consequently the root cap itself. Towards

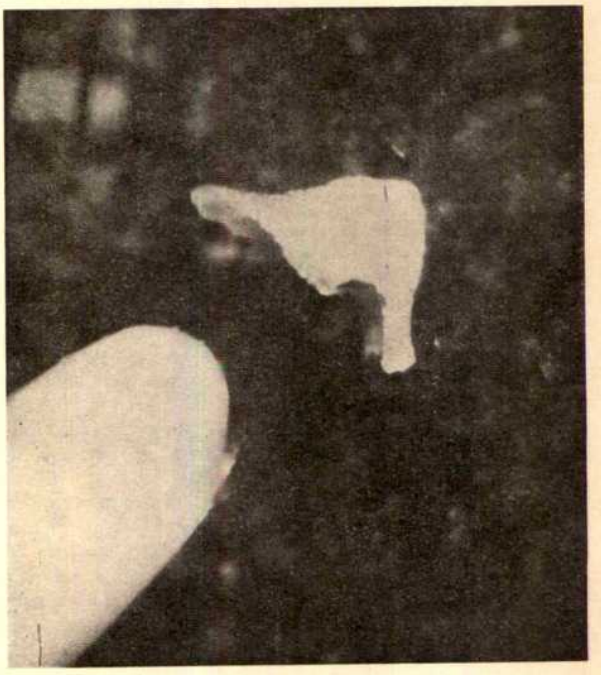

Fig. 1. A decapped maize root showing the clean undamaged surface of the meristem

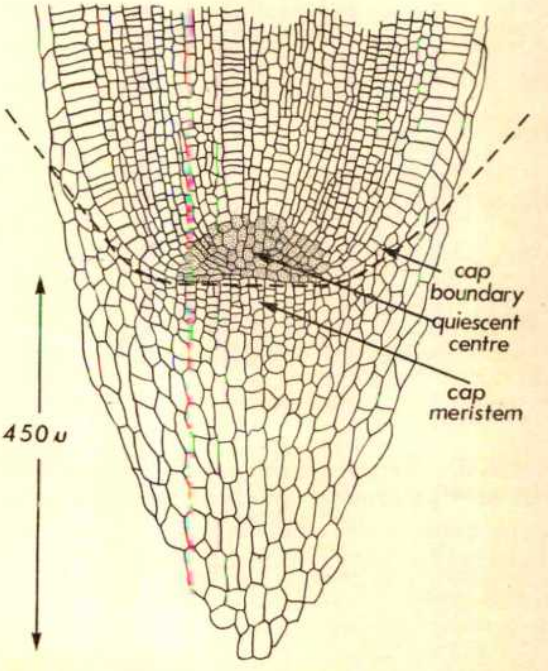

Fig. 2. Cell outline drawing of a median longitudinal section through a root tip of maize

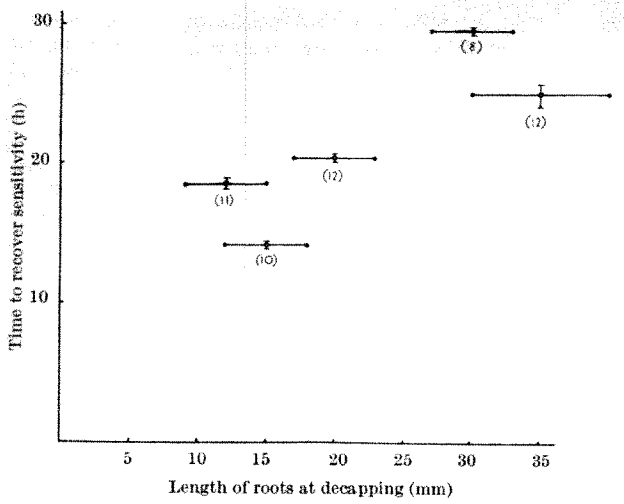

Fig. 3. Graph showing relationship between root length at decapping and time taken to recover geotropic sensitivity in maize roots at 20° C. The lengths of the lines through the means represent ± the standard error of the recovery times and the range of the root lengths in the samples. The numbers in brackets record the number of roots observed per sample

the end of regeneration the cap boundary is reformed and the quiescent centre re-established.

The ability to perceive gravity is regained somewhat abruptly and is correlated, so far as can at present be judged, with the regeneration of a major proportion of the root cap. Fig. 3 shows the relationship between root-length at decapping and the interval between decapping and the recovery of geotropic sensitivity in maize roots. The more rapid recovery of younger roots is correlated with the more rapid cap regeneration noted previously. In other experiments one of us (B. S.) has been able to remove a completely regenerated cap and to observe the regeneration process and recovery of geotropic sensitivity for the second time in the same root; this demonstrates clearly the lack of any damage to the root meristem by the decapping process.

The implications of these results are far-reaching. Clearly the root cap has no direct influence on root elongation and hence is unlikely to be the centre of root growth regulator production. But since it is the site of the perception of gravity it must in some way control growth regulator production in or movement from the tip meristem itself. Our results so far give no clue as to the nature of this control, and work on this problem is continuing.

Metabolic Activities of Isolated Heterocysts of the Blue-green Alga *Anabaena cylindrica*

Knowledge of the nature of the heterocysts of blue-green algae has been limited by the lack of suitable techniques for investigation of the physiology and biochemistry of these puzzling structures. The association of the presence of heterocysts with the ability to fix free nitrogen and the findings[1,2] that ammonia suppresses both nitrogen fixation and heterocyst formation have led to the suspicion that these cells might be involved in the nitrogen-fixation process. In this communication we report a successful technique of 'differential cell disruption' for the isolation of heterocysts of *Anabaena cylindrica*. We also present the first results concerning the metabolic activities of isolated heterocysts.

In making cell-free extracts of *A. cylindrica*[3] by smashing filaments in a French press[4], it was noticed that some of the heterocysts resisted breakage even at pressures exceeding 2,100 atm. At lower pressures (760 atm.) it was found that most of the heterocysts remained intact while all the vegetative cells were broken. Since then it has proved possible to obtain by this means a pure preparation of heterocysts, free of cell fragments and soluble cell material.

The experimental material was prepared from an exponentially growing culture[3] with developing heterocysts[1,5]. It was important to use young cultures free from both akinetes, which survive the smashing process, and extracellular mucilage, which interferes with the purification of the heterocyst fraction. The heterocyst frequency was about 6 per cent. The algal material was collected by centrifugation and forced through the pre-cooled French press at 760 atm. The suspension was homogenized a little at a time, in ten volumes of distilled water, using a Potter homogenizer. The suspended material was bulked and centrifuged at 1,300*g* for 10 min. Most of the soluble material and mucilage remained in the supernatant. The pellet was resuspended in distilled water, homogenized and centrifuged at 100*g* for 2 min, which precipitated the heterocysts but left most of the cell fragments in suspension. The supernatant was discarded and the heterocyst residue treated twice more as before. A heterocyst fraction practically free of soluble and particulate cell material was obtained. The main remaining contaminant was cell walls of broken heterocysts. The control fraction was prepared by identical treatment of algal material passed through the French press at a pressure not exceeding 95 atm., which caused the breakage of the filaments into short lengths but left the majority of the cells intact. This preparation is referred to as 'filament'. Both the final fractions were suspended in standard medium[3] and used immediately for experimental investigations.

Nitrogen fixation by heterocysts was tested by exposure to an atmosphere containing nitrogen-15 enriched nitrogen gas. Uptake of nitrogen-15 was measured by the method of Burris and Wilson[6]. The results obtained in the two experiments and shown in Table 1 demonstrate that no significant fixation occurred in the heterocyst fraction while the filaments fixed nitrogen vigorously.

Table 1. Fixation of ^{15}N-Nitrogen in Heterocyst and Filament Fractions of *Anabaena cylindrica*

Fraction	Atom per cent nitrogen-15 excess Exp. I	Exp. II
Heterocyst	0·004 (0·003)	0·000 (0·002)
	0·001	0·004
Filament	1·538 (1·616)	0·338 (0·368)
	1·693	0·397

Five-ml. suspension samples were incubated in Warburg flasks at 600 ft.-candles and 30° C with continuous shaking for 2 h. Gas phase: 0·1 atm. N_2 (containing 50 atom per cent ^{15}N in Exp. I and 20 atom per cent ^{15}N in Exp. II), 0·1 atm. oxygen; 0·02 atm. carbon dioxide; and the rest argon. Means in parentheses.

The photosynthetic capacity of heterocysts was investigated by exposing the fractions in the light to ^{14}C-labelled carbon dioxide. Carbon dioxide fixation was measured by radioactivity assay of samples collected on membrane filters. The results of the two experiments shown in Table 2 show that the heterocysts had no appreciable photosynthetic activity in contrast to the filaments, which became highly labelled.

Respiratory activity was measured by the direct manometric method of Warburg, and the results (Table 3) indicate that the heterocysts had greater respiratory activity than the filaments.

Table 2. Fixation of ^{14}C-Carbon Dioxide in Heterocyst and Filament Fractions of *Anabaena cylindrica*

Fraction	Radioactivity of cells (counts/min/μg cell N) Exp. I		Exp. II	
Heterocyst	12	(11)	0	(85)
	10		169	
Filament	11,040	(11,460)	58,750	(52,575)
	11,880		46,400	

Six-ml. suspension samples were incubated in Dickens-Simer flasks at 600 ft.-candles and 30° C with continuous shaking for 2 h. In each sealed flask ^{14}C-labelled carbon dioxide was generated by tipping 0·5 ml. 0·1 N hydrochloric acid placed in the side-arm into 0·5 ml. $NaHCO_3$ solution (containing 1·9 mg $NaHCO_3$) placed in the trough of the flask, thus providing 1 per cent carbon dioxide concentration (plus 2 μc. activity in Exp. I and 10 μc. activity in Exp. II) in the gas phase of each flask. Means in parentheses.

Table 3. Respiratory Activity of Heterocyst and Filament Fractions of *Anabaena cylindrica*

Fraction	μl. O_2 uptake/mg cell N/h	
Heterocyst	218·8	(230·2)
	241·3	
Filament	170·4	(159·4)
	148·4	

Four-ml. suspension samples were incubated in Warburg flasks, each provided with 0·5 ml. 12 per cent potassium hydroxide in the side-arm, in the dark at 30° C with continuous shaking. Means in parentheses.

Electron microscope investigations[5,7] with *A. cylindrica* and other blue-green algae have shown that the development of heterocysts from vegetative cells involves extensive changes in the fine structure, the most striking of which is the disorganization of the lamellar system. The paired lamellae (thylakoids), which are considered to be the structural units of the photosynthetic apparatus, the structure of which seems to be essential for the retention of the photosynthetic pigments, become open to the heterocyst and the unit membranes run singly, surrounding the vesicles or forming an elaborate branching system. Presumably the absence of photosynthetic activity in heterocysts results from the disorganization of the photosynthetic apparatus. The interesting finding that nitrogen fixing capacity is also absent in heterocysts is in good agreement with our previous report[3] that the site of nitrogen fixation in this alga is located at the photosynthetic lamellae. Our findings are in agreement with histochemical investigations[8,9] which indicate that heterocysts possess an active respiratory mechanism. Further investigations regarding the physiological and biochemical changes which occur during heterocyst formation are in progress.

This work was aided by grants from the Science Research Council. We thank Prof. G. E. Fogg for his advice.

Use of Lipase and Strepzyme for the Isolation of 'Protoplasts' from Fungal Mycelium

The isolation of protoplasts from bacteria[1], vegetative fungal cells[2-4] and plant tissues[5], following the use of enzymes digesting the cell wall, suggested that protoplast-like bodies might be obtained from resistant spore forms of fungi. It has recently been shown in this laboratory that free 'protoplasts' are also obtained when conidia of *Trichothecium roseum*[6] and *Fusarium culmorum*[7] are incubated in a solution containing the lytic enzyme preparation. Age of the spores seemed to be important for the digestion of the cell walls; under appropriate conditions, using young spores (3–4 days old), more than 90 per cent of the suspended conidia were transformed into 'protoplasts'. It was then suggested that spore protoplasts represent a satisfactory starting material for obtaining suspensions of free uniform protoplasts.

It was previously shown that Actinomycetes possess marked bacterial[8] and fungal lytic[9] properties. Following an investigation undertaken to explore the possibility of using enzyme preparations from actinomycetes in the digestion of fungal cell-walls, we found some interesting results. Cell-free shake flask culture filtrates of *Streptomyces RA* grown for 6–8 days at 28°, according to the method of Rodriguez Aguirre *et al.*[4], produced a lytic enzyme (strepzyme) which was very useful for the preparation of hyphal protoplasts of several species, including *Fusarium culmorum* mycelium.

It was noteworthy that protoplasts were not formed from cells of the more resistant forms, the fusaroid conidial cells, which in contrast were very susceptible to other strepzymes, for example *Micromonospora chalcea* enzymes. These results encouraged us to make a comparative study not only of the cell wall composition of the hyphal and spore cell walls but also of some of the enzymes present in the strepzyme preparations from the lytic organisms *Streptomyces RA* and *Micromonospora chalcea*. It was found that the conidial cell walls of *F. culmorum* contain less lipids than the mycelium cell wall[10]. However, it is well known that the total lipid content of fungus mycelium is so strongly affected by cultural conditions and age that any set of figures might be misleading. On the other hand, when the lipase activity was examined in the two cultures of actinomycetes mentioned here it was detected as very low, or practically no lipase activity in the strepzyme preparation from *Micromonospora AS* which is active on conidia and high lipase activity in the *Streptomyces RA* preparation.

These results may in part explain some of the previous observations on the digestion of the hyphal and spore cell walls and on the liberation of protoplasts.

Furthermore, in order to test and confirm the previous observations a commercial lipase preparation was used. The *Fusarium* mycelium was previously incubated for a short time (30 min) with 200 μg/ml. of pancreatic lipase enzyme (Sigma, U.S.A.) and then washed by centrifugation with a stabilizing buffered solution. The mycelium was again resuspended in the same solution and treated with the strepzyme preparation as already described. Surprisingly, and confirming the previous results, it was found that the combined action of lipase and the strepzyme from the *Micromonospora RA* successfully gave rise to the rapid formation of large numbers of mycelium protoplasts.

These findings, in addition to those described by various other workers when using combinations of chitinases and glucanases[11-13], may clearly speak in favour of the possibility of more frequent use of combinations of commercial and crude or partially purified microbial preparations for digestion of fungal cell walls and subsequent liberation of protoplasts, as well as for examination of the structural components of the cell walls released during degradation. Breakdown of cell walls by enzymes of one kind or another has been studied extensively in bacteria. Our experience of lytic activities suggests that combination of enzymes often shows a synergistic action, and these synergistic effects are apparent not only on living cells but also on dead cells and on their isolated cell walls. However, as has been suggested for the bacterial cell walls, a further assessment of the sites of action and relative specificities of the many enzymes which attack fungal cell walls

must await more information about chemical structure of their substrates—the walls themselves.

Semi-fossil Lichen Fungi in Scottish Hill Soils

Recent investigations[1] into the micromorphological features of hill soils in north-east Scotland have revealed the presence, within the soil profile, of what appear to be perithecia containing dark-coloured muriform spores. These perithecia are apparent in profiles from Meall-an-t-Slughain, Aberdeenshire (at heights of 2,050 ft. and 2,300 ft.), Ben Rinnes, Banffshire (2,500 ft.), and Morven Aberdeenshire (2,025 ft., 2,800 ft. (two) and 2,850 ft.). The profiles are developed on parent materials derived from both granite (Meall-an-t-Slughain and Ben Rinnes profiles) and basic igneous rocks (Morven profiles). Peat cover is either absent or amounts to no more than 2–3 in., except on one of the 2,800 ft. profiles on Morven, which has a peat cover 14 in. thick, the base of the peat being pollen dated within the Sub-Boreal period.

In many Ascomyceteae the whole ascus undergoes digestion at maturity, thus setting free the ascospores[2], and it is likely that this has occurred in the perithecium shown in Fig. 1. The size of the ascospores (Fig. 2) is rather variable, and though the majority are of the order of 40μ × 20μ some are considerably larger, up to 60μ in length. The size of the perithecia is also rather variable; the majority are approximately 160μ in diameter, but one from the 2,800 ft. Morven profile without peat cover was approximately 270μ in diameter. Some of the perithecia exhibit well-developed ostioles (Fig. 1).

Dr. T. D. V. Swinscow of the British Lichen Society and Mr. P. James of the Department of Botany, British Museum (Natural History), have confirmed (personal communication) our opinion that the structures described are the fungal components of a pyrenocarpic lichen, probably a species of *Polyblastia*[3], although it is impossible to recognize algal tissue in the soil sections.

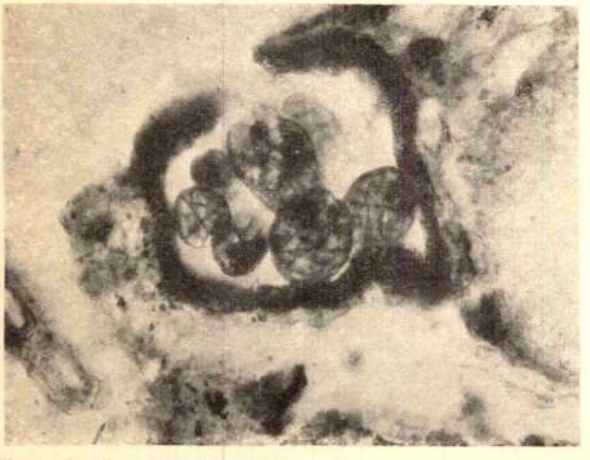

Fig. 1. Perithecium containing ascospores in thin soil section (× 270)

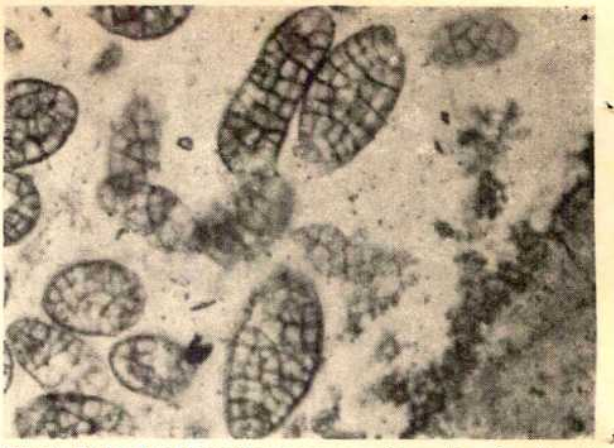

Fig. 2. Dark-coloured muriform ascospores with portion of perithecial wall in thin soil section (× 375)

Within the soil profile, the presence of either perithecia or ascospores has been noted to depths of 9 in. below the mineral surface, though in the case of the 2,800 ft. Morven profile not covered by peat they are present to a depth of 19 in. The Morven profile with peat cover has a thin iron pan at 8–10 in. below the mineral surface, and above this ascospores have been found in association with a pollen assemblage of Atlantic age.

This appears to be the first record of fungal components of a lichen, in a semi-fossil state.

We thank Mr. S. E. Durno of the Macaulay Institute for the pollen data.

Nitrogen Fixation by Lichens of Arid Soil Crusts

The nitrogen budgets for natural ecological systems are poorly understood, and the contribution of particular microflora in these associations has been only tentatively assessed[1–3]. This applies especially to arid zones where soils sometimes have a surface crust of lichens, some blue-green algae, and other cryptogams covering as much as 30 per cent of the total soil area. It is of considerable interest therefore to determine to what extent these lichens fix atmospheric nitrogen, since they might contribute appreciably to the maintenance of a favourable nitrogen balance in these areas.

About forty species of lichens are known to occur in the southern central arid zone in Australia, and twelve of the commonest were exposed to a gas mixture containing nitrogen enriched with nitrogen-15. Thus each lichen was incubated in a Warburg flask for 6 days at 21° C under artificial light, using the following gas mixture (in atmospheres): oxygen 0·2, nitrogen 0·2 (enriched with 35 atom per cent excess nitrogen-15), and helium 0·6. After this

period the contents of each flask were digested in acid, and converted to ammonia by distillation in a Markham apparatus and then to nitrogen gas which was analysed in an A.E.I. MS_2 mass spectrometer. Nine lichens, including *Parmelia adhaerens* Nyl, apud Cromb., *P. australiensis* Cromb., *P. semiviridis* (F.v.M. ex Nyl.) P. Bibby, *Caloplaca citrina* (Hoffm.) T. Fries, *Caloplaca* T. Fries sp., *Dermatocarpon hepaticum* (Lam.) Th. Fr., *Diploschistes scruposus* (Schreb.) Norm., and *Lecidea decipiens* Ach., with one unidentified species, showed no significant fixation. There was a significant incorporation of nitrogen gas, however, into *Collema coccophorus* Tuck. (0·97 and 0·69 atom per cent excess in duplicate samples), whereas *Lecidea crystalifera* Tayl. (0·022 atom per cent excess) and *Parmelia conspersa* (Ehrh.) Ach. (0·0073 atom per cent excess) had a marginal fixation only.

Collema coccophorus has a blue-green algal symbiont (*Nostoc* sp.). The lichen is minute but very widely distributed in the soil lichen crust. Shields, Mitchell and Drouet[4] have suggested that this species might fix nitrogen in the arid soil-crust in California. *Lecidea crystalifera*, which is also widespread in this area, has a green algal symbiont (*Protococcus*), hence the fixation associated with this lichen is of interest and will be investigated further. The lichen has a small squamulose thallus with long rhizoids penetrating up to 1 cm into the soil. *Parmelia adhaerens* similarly has a green algal symbiont (*Protococcus*), and occurs on rocks where it is fairly widespread.

This preliminary work suggests that the lichen crust may contribute appreciably to the nitrogen balance in Australian arid soils.

Measurement and Control of the Rate of Carbon Dioxide Assimilation by Glasshouse Crops

In recent experiments on the effect of environment on glasshouse crops, the net assimilation rate[1] and other indices of growth are found by measuring the dry weight and leaf area of plants sampled from the crop at intervals of the order of 10 days. During this time the intensity of the solar radiation reaching the plants fluctuates over the whole range between zero and the maximum value, so that a series of different combinations of light intensity and plant temperature occurs even if the air temperature and content of carbon dioxide are successfully maintained constant. Such experiments are thus difficult to interpret, especially as the rate of uptake of carbon dioxide by individual leaves is not related linearly to light intensity at all levels of temperature and carbon dioxide concentration[2], and even when light and all other environmental factors are held constant the rate may vary with time of day[3].

Interpretation is easier if the rate of assimilation of carbon dioxide can be measured during an interval of the order of 10 min rather than 10 days. In apparatus designed for this purpose, air is made to pass at a known rate through an enclosure containing a leaf[2,4] or a whole plant[4] and an infra-red gas analyser is used to measure the concentrations of carbon dioxide in the incoming and outgoing air. With difficulty, it might be possible to make a glasshouse sufficiently airtight for this method to be used to measure the net rate of assimilation of carbon dioxide by the plants contained in it.

An alternative approach is to make no attempt to seal the glasshouse or to make air flow through it at a constant rate. Instead, carbon dioxide is injected from a weighed cylinder at a rate varied to maintain a constant concentration, $[CO_2]_1$, in the glasshouse air, which is stirred by fans to distribute the gas uniformly. In the course of a time interval, Δt, the loss in weight, Δw_c, of the cylinder of carbon dioxide represents the net amount supplied to the plants and soil plus that lost by ventilation. To estimate the loss by ventilation, nitrous oxide, which is absent from the outside air and is not absorbed or produced by plants or soil, is injected into the glasshouse air from a weighed cylinder at a rate varied to maintain a concentration:

$$[N_2O]_1 = b([CO_2]_1 - [CO_2]_0) \qquad (1)$$

where b is a constant and $[CO_2]_0$ is the concentration of carbon dioxide in the air outside the glasshouse. The density, ρ, of nitrous oxide happens to equal that of carbon dioxide, although the technique does not depend on this being so. If Δw_n is the loss in weight of the cylinder of nitrous oxide during the time interval Δt, the rate of carbon dioxide uptake by the plants is:

$$C = S + \frac{1}{\Delta t}\left\{\Delta w_c - \frac{\Delta w_n}{b} + v\rho\left(\frac{\Delta[N_2O]_1}{b} - \Delta[CO_2]_1\right)\right\} \qquad (2)$$

where S is the rate of carbon dioxide output from the soil and v is the volume of the glasshouse. $\Delta[N_2O]_1$ and $\Delta[CO_2]_1$ represent any small changes in concentration between the beginning and end of the time interval due to imperfections in the control system.

In preliminary experiments, infra-red gas analysers have been used to measure $[CO_2]$ and $[N_2O]$, as the two gases have well-separated infra-red absorption bands. By using the signals from these analysers to give proportional control of the concentrations of the gases in the air of a small ($v \approx 5 \times 10^7$ cm^3) glasshouse, the fluctuations in the control system have been small enough for $\Delta[N_2O]_1$ and $\Delta[CO_2]_1$ to be negligible when Δt is of the order of 10–100 min, and when $[CO_2]_1$ is about 1,000 vol. per million, which is near the level required to give maximum uptake by leaves in bright light[2]. Under most weather conditions, changes in $[CO_2]_0$ also remain negligible for long periods and it is only necessary to confirm this by measurements at the beginning and end of each time interval. It is then possible to make $b = 1$ in equation (1) and equation (2) can be simplified to:

$$C = S + \frac{\Delta w_c - \Delta w_n}{\Delta t} \qquad (3)$$

For ordinary agricultural soils, S is small and can readily be measured[5]. Although it depends on temperature, it changes only slowly because of the large thermal inertia of the soil. It can be minimized, for experimental purposes, by growing the plants in sand, when the only source of carbon dioxide will be the roots and their associated micro-organisms.

Equations (2) and (3) thus provide a basis for measuring the rate of assimilation of carbon dioxide by all the plants in a glasshouse over an interval of time so short that the intensity of the solar radiation and the other components of the environment remain nearly constant. So also will the relevant physical properties of the plants, such as the leaf area index, the stomatal resistance and the diffusion pressure deficit in the tissues, and the chemical properties, such as the concentration of assimilates accumulated in the leaves.

By conducting a long series of these brief experiments at various intensities of solar radiation and at various levels of the environmental factors influencing the uptake of carbon dioxide, it would be possible to find the relation between this uptake and the factors on which it depends.

However, the complexity of this problem is such that, although the results might be of great botanical interest, solutions of practical value to horticulture may emerge only slowly, albeit faster than is possible using only the present techniques of growth analysis. The risk will remain that before the problem has been solved for one genotype, the plant breeders will have offered the horticulturists something new.

But a better solution is now in sight. If $C - S$, the net rate of uptake of carbon dioxide by the plants and soil, can be measured over a period of a few minutes, it is possible to feed back this information to a control system which then adjusts the environment until it produces the maximum possible value of $C - S$ attainable at the prevailing intensity of solar radiation. As S changes only very slowly, it is not necessary to measure it for the present purpose. At first, the control system could probably be designed to adjust the air temperature and $[CO_2]_1$, and in order to comply with equation (1) it would also be necessary to adjust $[N_2O]_1$.

The method could be used as an experimental tool to find the combinations of solar radiation, air temperature and concentration of carbon dioxide which produce maximum assimilation of carbon dioxide in various circumstances; but its most interesting potential use is in practical horticulture, where it could simply be used to ensure that during the hours of daylight a crop was at all times assimilating carbon dioxide at the maximum possible rate. This appears to be a promising basis for obtaining maximum crop production, provided the best levels of certain other factors, such as night temperature, are known from the results of orthodox experiments.

It is likely that the system would best be operated by a simple form of digital computer, which would call alternately for an adjustment of the temperature or $[CO_2]_1$ and $[N_2O]_1$, and for a measurement of $C - S$, with sufficient delay between the operations to allow for steady conditions to be reached.

The apparatus at present available is too large and expensive for use in practical horticulture, but computers are likely to become very much more compact[6] and a relatively cheap and simple device for the continuous measurement of $[CO_2]$ is at present being developed[7].

The control systems for the preliminary experiments were designed and made by G. E. Bowman and D. A. Browne, and the work was stimulated by discussions with L. G. Morris.

Selective Herbicidal Activity of Iodides

Investigations carried out here with the selective herbicide ioxynil (3,5-diiodo-4-hydroxybenzonitrile)[1] have shown its mode of action to be complex. The compound inhibits the Hill reaction in isolated chloroplasts, strongly uncouples oxidative phosphorylation, inhibits photosynthetic phosphorylation and when exposed to ultraviolet light there is evidence that free radicals are produced with the loss of iodine from the molecule[2,3]. In further investigations of the breakdown of ioxynil in soil and plant we have found that hydrolysis to 3,5-diiodo-4-hydroxybenzoic acid occurs with the amide as an intermediate product. The liberation of iodine in these systems has also been demonstrated.

In a separate investigation, solutions of the sodium salt of 3,5-diiodo-4-hydroxybenzoic acid applied to the soil caused little damage to most plant species but were very damaging to dwarf bean plants (*Phaseolus vulgaris*, var. 'Canadian Wonder'). As the acid became degraded in this plant and also in soil with liberation of iodide, experiments with iodide solutions were carried out. These showed that dwarf bean is very susceptible to iodide toxicity; foliar applications of sodium iodide (0·2 per cent) caused damage to the leaf tissues (see also ref. 4) and when the chemical was applied to the soil at the rate of 15 mg/3-in. pot (about 30 lb./acre) the seedlings were destroyed. Many other species of plants, however, were unaffected by iodide at this rate of soil treatment, thus indicating the possibility of selective herbicidal action. Experiments with some 50 weed and crop plant species from 20 families have confirmed this. Among weeds, annual nettle (*Urtica urens*) and fat hen (*Chenopodium album*) were found to be very susceptible to iodide, as was red and white clover (*Trifolium* spp.) and all other legumes tested. We have also achieved eradication in the field of well-established stinging nettle (*Urtica dioica*) with sodium iodide applied to the soil at rates of the order of 0·5 oz./yard^2 in one gallon of water. *Brassica* plants have been found to be very resistant to iodide, and a striking control of annual nettle growing in a cabbage crop can be achieved by application of sodium iodide to the soil at 20 lb./acre. We have also found that, while clover is susceptible, most species of grasses are tolerant, thus providing a simple means of removing clover from lawns. Such uses of iodides on the field scale, however, are likely to be uneconomic.

While the toxicity of iodides to certain plants is well known[5,6], the specific herbicidal selectivity here reported is a new finding. This might arise from differential uptake, though the results of our preliminary experiments carried out with two 'susceptible' and two 'resistant' species do not support this. In considering the chemical basis for this selectivity, it would appear that the fate of the iodide ion in susceptible and resistant species is different. In the former case, iodide could perhaps be oxidized more readily to iodine by peroxidase enzymes in a manner analogous to that thought to occur in the animal[7]. The iodine thus liberated within the tissues might then lead to the iodination of certain plant constituents. Reaction with tyrosine[8] might effectively deplete the level of this essential amino-acid in the amino-acid pool, and this, together with the simultaneous production of iodo derivatives, could have drastic effects on protein metabolism.

Correlation between Induced Extension-growth and Regeneration in Horseradish

Previous work has shown that initiation of bud and root primordia on roots of intact horseradish plants is influenced by the presence of a rosette of leaves, and that regeneration in isolated root segments is controlled by a growth factor produced during the extension of the buds first-formed following excision[1].

During an investigation of the effects of gibberellic acid on regenerating horseradish, further light was thrown

Table 1. Mean Number of Primordia formed per Lateral Root Scar

Month during which segments grown	Time from last spray treatment to excision of root segment (weeks)	Sprayed 4 times with water*	Sprayed 4 times with gibberellic acid (Na salt) 1 mg/ml. in water*
January	16	(2) 1·46†	(6) 1·59 ± 0·15
June	6	(5) 1·90 ± 0·26	(5) 1·01 ± 0·11
April	2	(4) 1·10 ± 0·26	(5) 0·09 ± 0·04

* Figures in parenthesis indicate the number of replicates.
† The standard error is not given where insufficient material was available.

on the nature of the correlation between stem extension-growth and regeneration. The main stem has been induced to grow in clonal horseradish plants treated with fortnightly sprays of an aqueous solution of the 75 per cent sodium salt of gibberellic acid. Plants were sprayed four times with 5 ml. of the solution, which contains 1 mg of the salt. Control plants were sprayed with the same quantity of distilled water. All seven treated plants elongated, whereas four out of five untreated plants remained as rosettes. Root segments 2 cm long and 2–5 mm thick were excised from some of the plants and were grown in the dark at 25° C on moist sand in Petri dishes. Segments from treated plants showed different regeneration patterns from the control segments; these results are expressed in Table 1 as mean number of primordia formed per lateral root scar. The regeneration pattern appears to be influenced by the length of time between the completion of treatment and the excision of the segments. It is also possible that these differences in root behaviour owe their origin to the use of clonal material of different age or to the different time of year in which experiments were carried out; seasonality in regenerating horseradish roots has been reported[2]; an age effect is suspected[3].

Gibberellic acid inhibits root and bud formation when applied directly to *Begonia* leaf disks[4], but it inhibits root initiation while promoting root extension-growth in pea and bean stem-cuttings[5]. It has also been reported to inhibit shoot formation in tobacco callus cultures at concentrations which stimulate callus growth[6]. The suggestion has also been made that gibberellic acid enhances the enzymatic destruction of indolyl-3-acetic acid[7]. In another series of experiments, unpublished results indicate that low concentrations (1 p.p.m.) of IAA can diminish the inhibition of root regeneration in treated horseradish plants. Table 1 indicates an improvement in regeneration ability in treated plants, the longer the interval between treatment and root excision. This would seem to indicate a possible recovery of a regeneration-controlling system from the inhibitory effect of gibberellic acid. As a working hypothesis, it could be suggested that gibberellic acid pre-treatment in causing extension-growth induces the formation by the elongating stem of either an antagonist to endogenous auxin, or, as seems more probable, the development of an auxin–oxidase mechanism in the roots. It is hoped that investigations in progress on indolyl-3-acetic acid oxidase mechanisms in horseradish will provide additional data which will explain these results.

Uptake of Small Particles by *Moniliformis dubius* (Acanthocephala)

The adults of *Moniliformis dubius* Meyer live as parasites in the small intestine of rats. Because they do not possess an alimentary canal, acanthocephalans, like cestodes, must obtain all their food through the surface of

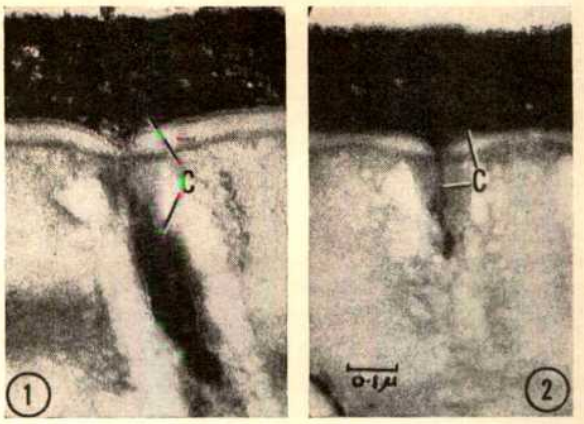

Fig. 1. Transverse section of cuticle of *M. dubius* showing an aggregation of particles of carbon and thorium dioxide within a vesicle below the cuticle (note layer of carbon and thorium dioxide (*C*) adhering to the outer surface of the cuticle)

Fig. 2. Transverse section of cuticle of *M. dubius* showing method of entry of the carbon and thorium dioxide particles (*C*)

their bodies. It is known that *M. dubius* is able to absorb directly through its surface a number of simple sugars[1,2] and some amino-acids, the latter sometimes against a concentration gradient[3,4].

Recent experiments carried out in this department have shown that *M. dubius* can also take up very small particles of solid matter in a manner that resembles pinocytosis. Figs. 1 and 2 are electronmicrographs of transverse sections of the cuticle of a male of *M. dubius* showing the uptake of a mass of small particles of carbon and thorium dioxide. The worm (aged 7 weeks) after its removal from the rat was immediately placed in a solution of 0·8 per cent sodium chloride containing carbon particles of diameter about 250 Å aggregating to 500–800 Å and thorium dioxide particles of diameter 70–250 Å. The temperature of the solution was maintained at 37° C. After 3 h the worm was removed, washed in warm saline, cut up into small pieces, fixed in 2 per cent osmium fixative and embedded in methacrylate. Sections were cut at 600 Å.

Confirmatory results showing that the uptake of small carbon particles occurs *in vivo* were obtained from electronmicrographs of the cuticle of worms removed from rats which had been dosed orally with saline solution containing carbon particles in the parasite.

Ubiquity of Melanin and the Effect of Phenylthiourea

Black or brown pigments are widespread among animals. Although they have been widely assumed to be melanin, they have not always proved to be so[1]. Their ubiquity is manifest in another way, by their widespread occurrence in a particular organism.

These pigments have been interpreted as protective, either by assisting concealment[2] or by acting as a screen against nocuous radiation[3–5], and in some cases they have been considered as energy transducers[6]. Such

adaptive significance is less evident in the case of the abundant black pigment that may occur in the viscera, and perhaps for this reason this pigment has been relatively neglected. Though an excretory significance has been proposed for melanin[6], some reluctance to accept the idea has been expressed[1]. Our investigations show that considerable quantities are indeed excreted, sometimes by surprising routes.

The ubiquity of such pigment is striking among amphibians. Some indication of this has already been reported in the case of *Xenopus*[7], but the account is incomplete, and further, the widespread distribution is more evident in the larvae of *Ambystoma*, *Rana pipiens* and *Rana temporaria*. In addition to the pigment that is obvious in the dermis, epidermis and eyes, it is present in the peritoneum, heart, walls of the major blood vessels, gut, liver, lungs, pronephros, mesonephros, spleen, pancreas, gills, neural tube and brain, membranous labyrinth, olfactory epithelium, the myotomes and in cartilage corpuscles.

The pigment in these sites is melanin, and is not to be confused with ommochromes or lipofuscins, in so far as it is insoluble in a wide range of solvents, including strong formic and sulphuric acids; it is readily oxidized and bleached, but not reduced; it reduces ammoniacal silver nitrate and appears dark green after staining with Nile blue under the conditions specified by Lillie[8].

Pigment in the epidermis, myotomes, gut and kidneys should not be confused with that contained in processes of dermal or peritoneal melanophores which insinuate themselves among the cells of these structures. Epidermal pigment in *Xenopus* is very scanty, being confined to the oral sucker and the tip of the tail, between stages 25 and 41 (Nieuwkoop and Faber); but it is abundant in the other species investigated, thus substantiating earlier observations[9–11]. Moreover, in *Rana pipiens* appearances strongly suggest that melanin granules are transferred from the processes of dermal melanophores into the epidermal cells among which they are insinuated (Fig. 1).

In the central nervous system, pigment is present not only in the meninges as previously recorded[7], but more significantly, we find that it occurs in the cerebral ventricles and neural canal as large clumps which appear to arise by compaction of granules cast off by the walls (Figs. 2 and 3).

The pigment in the myotomes appears as fine or coarse granules in the striated muscle fibres as well as in the myoblasts and in the surrounding connective tissue.

The effect of phenylthiourea is very significant. Its suppressive action on the melanin pigmentation of amphibians has been reported several times[7,12–16]. It is usually assumed to act directly on melanophores by inhibiting formation of their pigment and therefore its action in causing loss of colour has been held to show the existence of a considerable turnover of melanin[13]. This may appear surprising in a pigment that is chemically so notoriously inert. In *Xenopus*, it has been urged that there is no turnover[7,16], the pigment merely accumulating during normal development, so that the overt effect of phenylthiourea disappears by about stage 46. Its effect persists only in regenerating tissues that are still accumulating their complement of melanin and in which the melanophores consequently retain an active enzyme system.

Fig. 1. *Rana pipiens*. Transfer of melanin from a melanophore to an epidermal cell. From a larva 19 days after hatching. Two dark processes of a melanophore insinuated among epidermal cells appear on right. The upper process makes intimate contact with an epidermal cell into which it is apparently transferring two granules of pigment. Fixed 10 per cent formol; Mallory's triple stain. Scale, 5μ

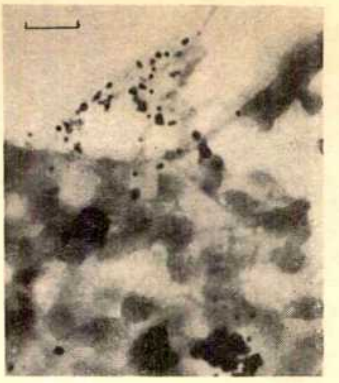

Fig. 2. *Xenopus laevis*. Discharge of melanin into the ventricle of the diencephalon. The lower portion of photograph shows melanin in the lateral wall of the diencephalon, from which secretion containing pigment may be seen passing off. Fixed 10 per cent formol. Stained by Masson's argentaffin reaction, counterstained in Mallory's triple stain. Scale, 8μ

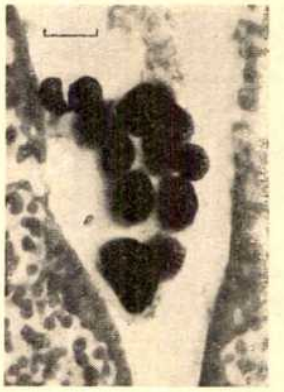

Fig. 3. *Xenopus laevis*. Compacted melanin in ventricle of medulla. Fixed 10 per cent formol; Mallory's triple stain. Scale, 18μ

The situation is not so easily explained. Our experiments on *Xenopus* confirm that the marked effect of phenylthiourea on pigmentation is relatively short-lived, beginning at room temperature at about stage 25 and persisting until about stage 41. Thereafter it progressively declines, although its effect on pigmentation can still be detected in the meninges and dermis until about stage 49. Nevertheless, melanin slowly accumulates up to the time of metamorphosis (the latest stage we have investigated) in most of the areas already listed here, with the notable exception of the gut and the brain.

Most significantly, however, from the very earliest stages the pigment in some situations is unaffected by phenylthiourea. This is not wholly due to the fact that some pigment is carried over from the egg, for the pigment that appears later in certain situations remains unaffected, or is even increased in amount by the drug. Thus, pigmentation of the eye, dermis, peritoneum, meninges and olfactory sacs is diminished by it, whereas that of the brain, gut, liver, myotomes and membranous labyrinth is unaffected or increased. The latter 'aberrant' effect appears very clearly in the two species of *Rana*; more-

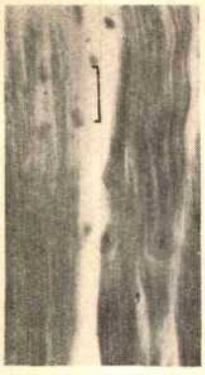

Fig. 4

Fig. 5

Fig. 4. *Rana pipiens*. Striated muscle and connective tissue of myotomes in a larva 19 days after hatching. Fixed 10 per cent formol; Mallory's triple stain. Scale, 15μ

Fig. 5. *Rana pipiens*. Melanin in striated muscle and connective tissue of myotomes as it appears in a larva 19 days after hatching, which has been treated from the time of hatching with 0·01 per cent phenylthiourea. Fixed 10 per cent formol; Mallory's triple stain. Scale, 15μ

over, here it also appears in the kidneys, particularly in the pronephros. In *Rana pipiens*, the amount of pigment appearing in the muscle fibres and surrounding connective tissue of the myotomes is strikingly increased after phenylthiourea (Figs. 4 and 5).

In the instance of the gut, central nervous system and kidney tubules, the histological picture presented is of granules of pigment being cast into the lumen from the free border of the surrounding epithelium. The same is seen in animals that have been starved, or fed on milk powder, so that in the case of the gut, absorption is an unlikely interpretation. Pigment appears to accumulate in the myotomes and epidermis, though in the latter case some will be lost by desquamation.

Much melanin is therefore being excreted and the process occurs particularly in the areas apparently unaffected by phenylthiourea or in those where pigmentation may be increased by it. The areas where melanin is diminished after phenylthiourea are those where pigment is being formed. During development active excretion is roughly contemporaneous with rapid pigment formation so that rapid turnover clearly occurs at some stages and the overall pigmentation will be determined by the amount of pigment excreted as well as by the amount formed and accumulated.

Phenylthiourea, therefore, not only affects formation but exerts other effects on melanin pigmentation. Its precise mode of action is still a matter of argument, so that considerable circumspection is necessary in interpreting its effects.

A Protozoan Parasite of *Molgula manhattensis* (De Kay) (Urochordata)

During the course of an investigation into oogenesis in the ascidian *Molgula manhattensis* a protozoan was discovered parasitizing a few of the nearly mature and fully mature eggs of one gonad. The ascidian which contained the infected gonad was one of several of the same species taken from Plymouth Sound in June 1963. Although there was insufficient material to classify the parasite accurately, the similarity of the observed stages to certain stages in the life-cycles of the Haplosporidia suggests that it is allied to this group[1,2].

The infected gonad had been excised, fixed and sectioned before the parasite was discovered, and as the remaining parts of the specimen had been discarded it was not possible to discover whether any other organs were infected. Fixation was carried out in Lillie's acetic–alcohol formalin[3]. It was found after sectioning normal gonads from other specimens that the fixative caused some distortion of the egg contents; it is therefore possible that the structure of the parasite may have been similarly affected.

The Feulgen reaction followed by staining in fast green gave the clearest picture of the parasite's structure; therefore the following description has been made from sections subjected to this procedure.

The stages of the parasite comprised plasmodia, cysts which contained uninucleate spores, or spores and plasmodia, and structures intermediate in development between plasmodia and cysts.

Each plasmodium was spherical and surrounded by a thin unbroken membrane. The diameter varied from 5 to 20μ. The cytoplasm contained an eccentrically sited vacuole, and from 4 to approximately 64 nuclei, all of which were oval and were coloured evenly by the Feulgen reaction. Their number increased with the diameter of the plasmodia (Fig. 1).

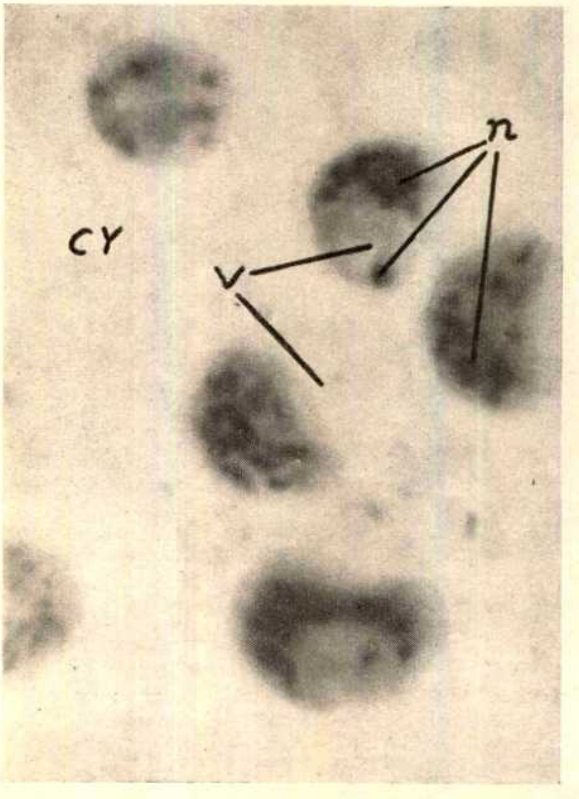

Fig. 1. Plasmodia in cytoplasm (*cy*) of mature egg. The nuclei (*n*) appear as dark oval bodies, the plasmodial vacuole (*v*) as a diffuse unstained area (× 3,400)

Stages greater than 20μ in diameter were encysted. Each cyst wall was formed from the thickened plasmodial membrane which had become irregular in outline. The greater portion of the cytoplasm had disappeared, and each nucleus together with a small portion of the remaining cytoplasm had developed directly into a spore (Fig. 2). The number of spores per cyst was estimated as being between 150 and 200. Each spore was oval and measured 3μ × 1·5μ. One end was coloured by the Feulgen reaction, the other was stained faintly by the fast green. No other structural details could be observed.

It was considered reasonable to assume that the Feulgen positive region of each spore contained the nucleus. Presumably a thin membrane surrounded each spore, but was so delicate that it was not demonstrable by the procedure used.

Some of the larger cysts contained a few small plasmodia as well as spores (Fig. 2), and a few of these cysts had ruptured membranes. The plasmodia within the cysts were spherical, 5–8μ in diameter and contained 4–8 nuclei. A plasmodial membrane was not observed.

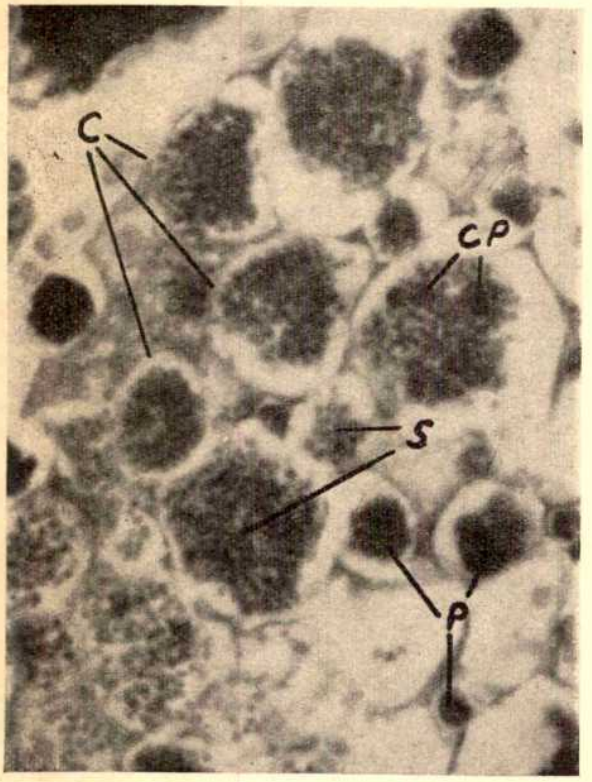

Fig. 2. Portion of heavily infected egg containing plasmodia (*p*) and cysts (*c*). Some of the cysts contain plasmodia (*cp*) as well as spores (*s*) (× 1,300)

The degree of infection varied considerably. A few infected eggs contained only plasmodia scattered between the yolk platelets, whereas the majority contained cysts, plasmodia and intermediate stages. These eggs were distended; the yolk platelets had either degenerated or perhaps been consumed by the parasite as a source of nourishment.

Growth of Processes from Single Isolated Dorsal Root Ganglion Cells of Young Rats

Cavanagh[1], using the technique described by Nakai[2], has filmed the growth of isolated cells from chick-embryo dorsal root ganglia. By the application of a similar technique, growth of new processes has been shown in isolated cells from dorsal root ganglia of new-born rats up to 7 days old. The Wag-strain rats were decapitated, the spinal cord separated, and the ganglia teased out with needles under microscopic vision. The ganglia were torn open to release a large number of cells into the culture Medium 199 (ref. 3) in well slides. The slides were covered with cover-slips, sealed with petroleum jelly, and incubated at 37° C. They were examined and photographed under phase-contrast microscopy immediately on incubation (20 preparations), and then three times a week; in this series, cultures from 15 young rats, and 11 adult rats, were observed between 7 and 14 days after the beginning of incubation. No processes were visible in the freshly incubated cells, nor were they in the cells from the adult ganglia (Fig. 1). However, in 13 out of 15 preparations

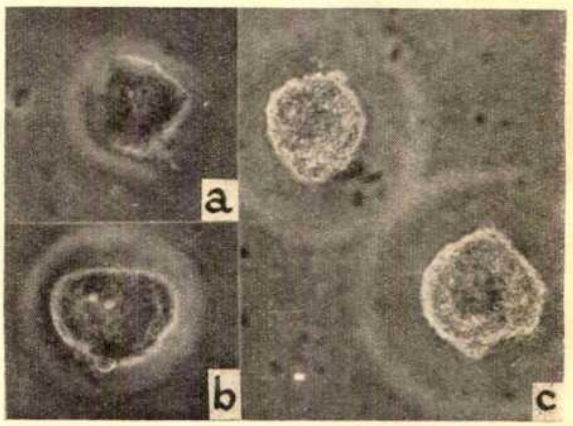

Fig. 1. Isolated dorsal root ganglion cells of rat. *a*, *b*, Freshly isolated from 4-day-old rat; *c*, incubated for 14 days from a 3-month-old rat. In both figures the cells are photographed under phase-contrast microscopy and are in Medium 199. The calibration is given by the horizontal bar in Fig. 2 (20μ)

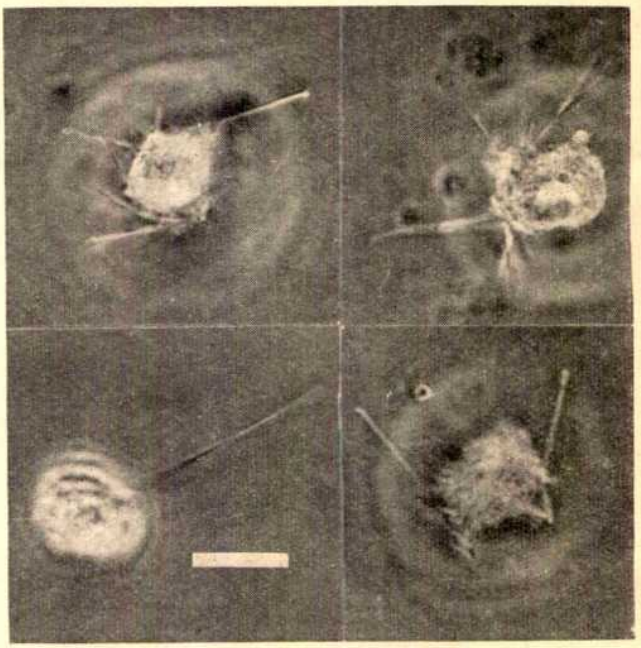

Fig. 2. Similar cells, isolated from 4-day-old rats and incubated for 14 days. Note the processes, with their cones

of cells from young rats, straight or angular processes of length equivalent to from one-quarter to two times the cell body diameter could be seen in about a quarter to a third of the cells in each preparation (Fig. 2). Growth cones could sometimes be seen either at the tips of the processes or where they changed direction.

I thank Dr. J. B. Cavanagh for his advice.

Metabolism of Gammexane in Flies, Ticks and Locusts

THE insecticide gammexane is known to be converted into water-soluble compounds in a variety of invertebrates[1], but the nature of these metabolites is not known. Some indication of their structure has been given by Bradbury and Standen[2], who obtained a mixture of dichlorothiophenols after the alkaline hydrolysis of excreta from gammexane poisoned flies. It is also known that homogenates of flies require glutathione if enzymatic conversion of gammexane to water-soluble derivatives is to occur[2]. These results have suggested that a compound like *S*-(pentachloro*cyclo*hexyl)glutathione might be a metabolite, and this hypothesis is supported by the presence of highly active enzymes in a variety of insects which catalyse the condensation of other chloro-compounds with glutathione[3].

We have attempted to identify such a metabolite in ticks, houseflies or locusts dosed with gammexane or in enzyme extracts fortified with glutathione, but have found the major metabolic product in each case to be an aromatized molecule which appears identical with *S*-(2,4-dichlorophenyl)glutathione.

The synthesis of this compound was achieved by a variation of the general method of preparing *S*-aryl cysteines[4] in which the cuprous mercaptide of glutathione was treated with diazotized 2,4-dichloraniline. The product was isolated by isoelectric precipitation at *p*H 3 and crystallized from ethanol–water. The *S*-(2,4-dichlorophenyl)glutathione had m.p. 215° C decomp. and $[\alpha]_D^{20} = 0 \pm 5$ ($c = 1$ in 0·1 N sodium hydroxide). Found: C, 42·5; H, 4·6; N, 8·4; Cl, 16·0; S, 7·0 per cent. $C_{16}H_{19}N_3O_6Cl_2S$ requires: C, 42·5; H, 4·2; N, 9·3; Cl, 15·7; S, 7·1 per cent. This compound was also isolated in good yield from unsuccessful attempts to prepare *S*-(pentachloro*cyclo*hexyl)glutathione from gammexane and glutathione in liquid ammonia as described for other glutathione derivatives[5]. The *S*-(2,4-dichlorophenyl)glutathione had an absorption spectrum similar to that of the analogous cysteine derivative with λ_{max} 258 mμ, ε_{max} 6,600 in 0·1 N sodium hydroxide and λ_{max} 257 mμ, ε_{max} 5,600 in 0·1 N hydrochloric acid. After hydrolysis at 100° C with 2 N hydrochloric acid for 4 h, 2,4-dichlorophenylcysteine was isolated identical with a sample prepared according to Parke[4].

Gas chromatographic analyses of cattle ticks (*Boophilus decoloratus*) kept at 35° C overnight showed that only 77 per cent (64–96 per cent) of a 10 μg topical dose of gammexane was recoverable unchanged. In similar experiments with ^{14}C-gammexane 28 per cent (6–30 per cent) of the dose was found in the water-soluble fraction after partitioning the homogenized ticks between water and xylene.

Enzymatic experiments were carried out with homogenates of cattle ticks, houseflies, or locust fat body containing 5 mM glutathione at *p*H values between 5 and 8 and with sufficient ^{14}C-gammexane to give a concentration of 5 mM. Water-soluble radioactive products were only formed when both glutathione and enzyme were present. When the reaction mixtures were examined chromatographically (Table 1) or by ionophoresis at *p*H 2, 3, 5, 7 and 8, a major part of the metabolized material was identical in behaviour with reference 2,4-dichlorophenylglutathione.

Table 1. R_F VALUES OF POSSIBLE GAMMEXANE METABOLITES

	S-(2,4-dichlorophenyl)-cysteine	*S*-(2,4-dichlorophenyl)-glutathione
Collidine–lutidine–H_2O, 1:1:1	0·75	0·50
n-Butanol–acetic acid–H_2O, 4:1:5	0·70	0·60
Pyridine–*n*-butanol–H_2O, 1:1:1	0·80	0·70
n-Propanol–ammonia sg. 88, 7:3	0·80	0·65
2-Butanone–H_2O, 1:1	0·05	0·05

The characteristics of this enzymatic reaction differed from those associated with the same enzyme sources when 2,4-dinitrochlorobenzene or *p*-nitrobenzyl chloride were used as substrates[2]. While the reaction rate with these substrates was constant over several hours, the reaction rate with gammexane fell off to a negligible value in 2–5 min. Moreover, the conversion of gammexane to a water-soluble derivative was not significantly affected by 0·1 mM bromsulphonphthalein, which completely inhibits the enzyme-catalysed reaction between *p*-nitrobenzyl chloride or 2,4-dinitrochlorobenzene and glutathione[3].

The formation of an aromatic derivative from gammexane is in general agreement with Bradbury's observation[1] that 4–6 atoms of chlorine are lost from gammexane when it forms water-soluble metabolites. On the other hand, it is difficult to reconcile the formation of a single major metabolite with Bradbury and Standen's isolation[2] of substantial amounts of 2,5- as well as 2,4-dichlorothiophenols from hydrolysed fly excreta unless the corresponding isomeric *S*-arylglutathiones are identical in all our chromatographic and ionophoretic systems or unless 2,4-dichlorophenylglutathione is an artefact formed from a very labile pentachloro*cyclo*hexylglutathione.

It has been suggested[6], on the basis of a colorimetric estimation procedure, that pentachloro*cyclo*hexene is a major but transient metabolite of gammexane in resistant flies, though this has not been confirmed by isotopic techniques. We have therefore applied the Schechter-Hornstein[7] colorimetric procedure to 2,4-dichlorophenylglutathione to see if it would give a false indication of pentachloro*cyclo*hexene. The metabolite did not interfere significantly in the reaction, but it would be desirable to investigate its probable precursor, pentachloro*cyclo*hexylglutathione, as the 'apparent' pentachloro*cyclo*hexene found by Sternberg and Kearns[6].

We are grateful to the Anti Locust Research Centre for financial assistance and to the Cooper Technical Bureau for supplies of cattle ticks.

ENTOMOLOGY

Increases in the Incidence of *Atherigona indica infuscata* Emden Diptera (Anthomyiidae) on Sorghum due to Spraying

Central shoot fly, *Atherigona indica infuscata* Emd., is a serious pest of sorghum in the Old World. It is extremely common in East Africa and has been recorded from *Brachiaria brizantha*[1], *Sorghum verticilliflorum*, *Eleusine coracana*, *Pennisetum typhoides*, *Zea mays*[2], as well as cultivated sorghums. The fly is a pest of the young seedlings, and causes severe damage to the growing point. This usually leads to tillering; these tillers may or may not escape subsequent attack. If the former, the only effect is to lengthen the maturation period; if the latter, yield may be seriously affected.

Swaine and Wyatt[3] obtained some control of the pest using weekly applications of DDT/benzene hexachloride dusts in Tanzania. Ingram[4] has reported failure to control the pest at Serere, Uganda, with DDT, and was unable to correlate the degree of infestation with yields. Clinton[5] also found that insecticidal sprays failed to afford control of this Anthomyid in the Sudan. Wheatley[6], working in Kenya, has obtained control with DDT/benzene hexachloride dusts on late plantings.

In subsequent experiments at Serere, we tested three insecticides against a control treatment, namely, DDT (25 per cent ml.) at 1 lb. a.i. per acre, carbaryl (85 per cent sprayable) at 2 lb. a.i. per acre and fenitrothion (50 per cent ml.) at 1 lb. a.i. per acre. Sprays were applied 7 and 14 days from germination to sorghum planted at three dates separated by 4-day intervals. Two varieties were used, 'Serena' (*SB* 68) which shows field resistance to the pest, and 'Combine Kaffir' (*CK* 60) which is susceptible. The two experiments had different error variances and were analysed separately. Counts on random rows within harvest plots, protected by the appropriate sprayed guard rows, were made. Results are shown in Table 1.

Table 1. Mean Number of Shoots killed by *A. indica* at Fourteen Days

Planting date	Control	Carbaryl	Fenitrothion	DDT	Mean
		A. 'Serena'			
1	69	56	55	51	58
2	47	68	38	86	60
3	137	303	145	286	218
Mean	84	143	79	141	112
S.E. treatment mean, ± 27·3.					
		B. 'Combine Kaffir' 60			
1	64	60	34	48	52
2	70	72	66	132	86
3	87	171	127	199	146
Mean	74	101	76	126	94
S.E. treatment mean, ± 15·2.					

In both varieties late planting leads to an increase in the number of plants attacked ($P < 0.001$), but DDT and carbaryl also increase the pest attack compared with the control. Fenitrothion had no effect. The increased attack on the DDT and carbaryl treatments was significant at $P < 0.01$ on *CK* 60 and at $P < 0.05$ on 'Serena'. The effect of late planting has been observed previously, but the insecticidal effect was unexpected. DDT and carbaryl apparently control parasites or predators of *Atherigona* more efficiently than the pest itself, leading to an increase in crop damage.

There was no significant difference in the degree of infestation in the two varieties, although *CK* 60 shows less attack and the difference approaches significance. Analysis of yield data from both varieties showed that there was no significant difference between the insecticidal treatments for either variety. The regression of yield on dead hearts was significant at the 5 per cent level for *CK* 60, but not for 'Serena'. This confirms the apparent field resistance of 'Serena'. The mechanism of varietal resistance is probably a reduction in the level of attack on the secondary tillers of 'Serena'. Secondary tillers of *CK* 60 are heavily attacked, and yields are consequently affected.

Such resistance is probably possessed by many of the indigenous sorghum varieties of East Africa, and explains Ingram's result. Introduced varieties from areas where the pest does not occur are not so resistant.

MICROBIOLOGY

Comparison of Oxygen Demand Rates and Oxygen Utilization Rates

The rate of oxygen consumption by a bacterial suspension can be measured by observing the change in concentration of oxygen in the air in contact with the culture or dissolved in the suspension. The rate of consumption is known as the oxygen demand rate which Gaden[1] defines as the maximum use of oxygen by a culture in an ideal environment. Oxygen utilization is defined by the author as the terminal use of oxygen in respiration, that is, the formation of water. In this investigation both oxygen demand and oxygen utilization of a culture of *Pseudomonas fluorescens* during respiration only were simultaneously measured.

To act as a hydrogen acceptor in respiration, oxygen must pass from the gaseous state to the dissolved state and then through a number of interfaces and obstacles all of which provide considerable resistance to its passage. Theoretically, then, oxygen utilization may occur at the same rate as oxygen demand, but should lag oxygen demand by a time factor which is dependent on the magnitude of the resistance to oxygen transfer. The purpose of the investigation reported here was to test this hypothesis.

To measure the rate at which water is formed in an environment that contains water it is necessary to use a tagged oxygen atom. The heavy isotope, oxygen-18, was used in this investigation. The method of using oxygen-18 to measure utilization rate, that is, the formation of $H_2{}^{18}O$, has already been described[2].

Manometric determinations of oxygen demand were made simultaneously with the oxygen utilization tests. The apparatus used automatically recorded the oxygen demand of the respiring culture[3].

The results of oxygen utilization and oxygen demand tests for two runs are shown in Fig. 1. It is apparent that oxygen utilization does not proceed at the same rate as oxygen demand, at least for the time period of these tests. It is evident, however, that the rate of utilization increases through the test. This is especially evident in run *B*, where the rate of utilization increases and the oxygen demand rate is constant. In run *C* the oxygen demand rate decreased during the final minutes of the run, and so the increase in oxygen utilization rate is not as

Table 1. Percentage Production of $H_2{}^{18}O$

Run	Sample No.	Rate of $H_2{}^{18}O$ produced / Rate of ^{18}O consumed (per cent)
B	2	22·4
	3	34·8
	4	42·7
C	5	25·1
	6	17·4
	7	44·0

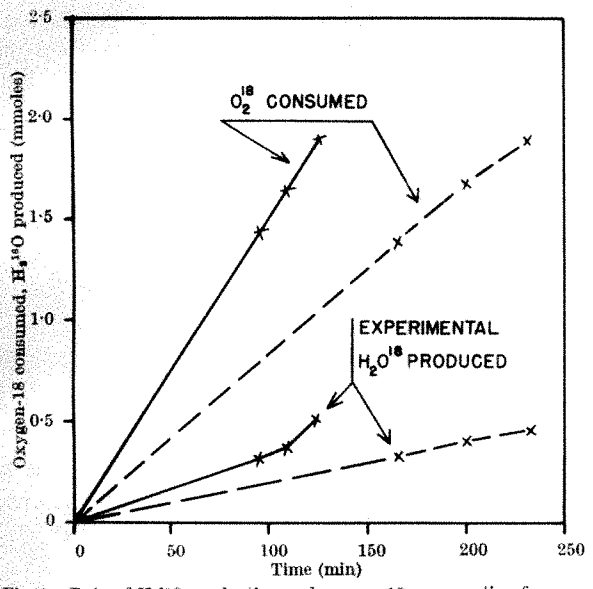

Fig. 1. Rate of $H_2{}^{18}O$ production and oxygen-18 consumption for runs *B* (——) and *C* (— — —)

obvious. However, if the rate of $H_2{}^{18}O$ production is divided by the rate of consumption of oxygen-18 and converted to a percentage as shown in Table 1, it is evident that the rate of utilization is increasing in both the runs. There is no apparent explanation for the reduction in the percentage for sample 6.

This exploratory work indicates that there is a lag between oxygen demand and oxygen utilization. As the bacteria were deprived of oxygen for approximately 2 h before the test was undertaken, it is possible that this lag is merely an indication that oxygen must first be used to replenish stored oxygen, after which it is then utilized as a hydrogen acceptor. Since oxygen utilization is closely associated with product formation, the lag determined here may be similar to the lag in product formation reported by Gaden[4] or Finn[5].

This investigation was supported in part by grant *GP*–355 from the National Science Foundation.

Enhanced Growth of *Bordetella pertussis* in Dialysis Culture

THE propagation of phase-1 *Bordetella pertussis* for vaccine production has been the subject of considerable experimentation. Some investigations[1–4] dealt with a description of media which do not contain blood, yet few studies were directed to population development or to methods for achieving high-titred cultures. Pollock[5] observed that the growth of the *Pertussis* organism in liquid media was enhanced by the presence of a diphtheroid; and Holt[6] reported the recovery of high concentrations of *B. pertussis* from a solid-liquid biphasic system.

Recently, Gerhardt and Gallup[7] described a dialysis flask useful for the concentrated culture of micro-organisms. In this twin-chambered flask, designed with a dialysis membrane sandwiched between a sterile reservoir of medium and the inoculated culture medium, concentration ratios for some microbial species approached the theoretical limit for the reservoir-culture volume ratio (10 : 1) used. This communication reports experiments designed to test the possibility that the concentration advantages of dialysis culture might be coupled with symbiotic association to achieve highly concentrated populations of *B. pertussis*.

B. pertussis phase-1 (obtained from R. D. Wende, Houston City Health Laboratories, Texas) was seeded into a biphasic culture vessel[8] which consisted of a 250 ml. Erlenmeyer flask containing 48 ml. of Cohen and Wheeler[2] agar medium overlaid with 12·5 ml. of liquid medium. This culture was incubated at 37° C on a reciprocal shaker (Eberbach, Ann Arbor, Michigan) for 24 h, and 1·0 ml. was inoculated into 100 ml. of Cohen and Wheeler medium contained in the culture portion of a twin-chambered dialysis flask (obtained through the courtesy of Prof. P Gerhardt, University of Michigan, Ann Arbor). A cellulose membrane (Visking Co., Chicago) separated the culture portion of the vessel from 1 l. of Cohen and Wheeler medium contained in the reservoir below. The reservoir was inoculated with *Corynebacterium pseudodiphtheriticum* cultivated in a manner similar to that described for *B. pertussis*. In non-symbiotic experiments, either the reservoir of the dialysis flask was not inoculated (dialysis culture) or it was separated from the culture above by a disk of stainless steel (control culture). The flask was mounted on to a rotary shaker (New Brunswick Scientific, New Brunswick, New Jersey) operated at 200 r.p.m. through a 1-in. stroke and was incubated at 37° C for 60 h. Samples were removed periodically from the upper culture chamber for determination of viable cells of *B. pertussis*: appropriate dilutions in 0·1 per cent (w/v) tryptone were spread over prepared plates of Cohen and Wheeler agar medium, and colony counts were made after incubation at 37° C for 48 h.

Typical experiments are shown in Fig. 1. The results indicate not only that dialysis culture was successful for the concentrated culture of *B. pertussis* but also that the provision for dialytic symbiosis resulted in significantly higher cell yields than obtainable in dialysis culture alone. The nature of the symbiotic relationship between *B. pertussis* and *C. pseudodiphtheriticum* is not known. Pollock[9] suggested that growth stimulation in symbiotic culture might be explained by the removal, by diphtheroids, of toxic fatty acids released by *B. pertussis* during growth. However, when the reservoir of the dialysis flask contained only the filtrate from a culture of *C. pseudodiphtheriticum*, the growth of *B. pertussis* was equivalent to that found under conditions of dialytic symbiosis. The results also indicate the survival advantage gained by cells grown in dialysis culture: *B. pertussis*

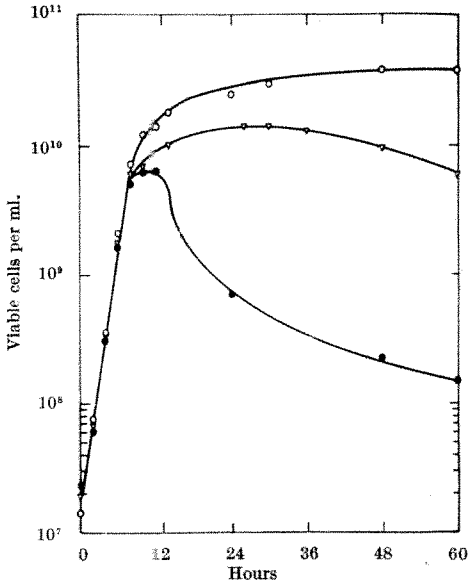

Fig. 1. Growth curves of *Bordetella pertussis* in liquid culture. ●, Control; ▽, dialysis culture; ○, dialytic symbiosis culture with *Corynebacterium pseudodiphtheriticum*

grown in the control culture reached a population peak at 12 h and then declined rapidly in numbers, while growth in the dialysis or dialytic symbiosis cultures continued to 24 h or more, then levelled off. Similar findings have been reported for *Serratia marcescens* grown in dialysis culture[7].

Influence of Incubation Temperature and of Storage on the Viability of Fungal Spores damaged by Phenol

The evidence for an improved revival of damaged bacteria on incubation at temperatures below the optimal for the undamaged species applies mainly to irradiated cells (see, for example, refs. 1 and 2), but optimal revival at 27°–29° C of *E. coli* damaged by phenol has also been reported[3,4]. The storage of irradiated bacteria and mammalian cells at sub-optimal growth temperature for some hours leads to an increase in the number of survivors[5]. We find that storage has a beneficial effect, but not a lower optimal incubation temperature with fungal spores damaged by phenol.

Suspensions containing $6{\cdot}25 \times 10^6$ *Penicillium notatum* or 5×10^6 *Aspergillus niger* spores per ml.[6,7] were mixed with equal volumes of phenol solutions at 25° C. These were filtered through 'Oxoid' membrane filters after definite contact times; the spores were washed with water until the filtrate was free of phenol and then re-suspended in water. One-drop aliquots were added to equal volumes of double-strength 'Oxoid' Sabourand liquid medium on each of four microscope slides which, after placing in Petri dishes containing wet cotton wool, were incubated at the required temperature. Differential counts of 100 germinating and non-germinating spores were made on replicate slides after 8 h and, when hyphal growth was not too dense to permit accurate counting, at intervals up to 24 h.

To examine the effect of storage, spores were treated with 1 per cent phenol, separated, washed and re-suspended in water. Portions of these *A. niger* suspensions were stored at 5°, 23·5°, 30°, 36°, 40° and 50° C for 6–48 h, and *P. notatum* suspensions at 5°, 15°, 25°, 28°, 31° and 37° C for 5–25 h. Replicate slides were prepared and incubated at the optimal growth temperatures: *A. niger* at 36° C, *P. notatum* at 28° C. Controls were prepared by plating out suspensions directly after contact with phenol.

The optimal incubation temperature of spores damaged by phenol was the same as that for the undamaged spores (Fig. 1). Damaged spores, however, took longer to germinate than those not damaged; at optimal temperatures they took 2 h or more to reach maximum survival levels. At temperatures above or below the optima the differences between these times were even greater, but the respective maximum percentage survival levels were obtained with both damaged and undamaged spores on prolonged incubation. The rate of germination and the viability fell more rapidly at temperatures above than below the optima.

Storage of damaged spores in water for some hours at temperatures ranging from below the optima to a little above gave improved revival (Fig. 2). In general, an increase in the temperature of storage resulted in a shorter period being required for maximum revival. Storage at temperatures just below the optima for about 24 h gave some of the best recoveries. This effect may

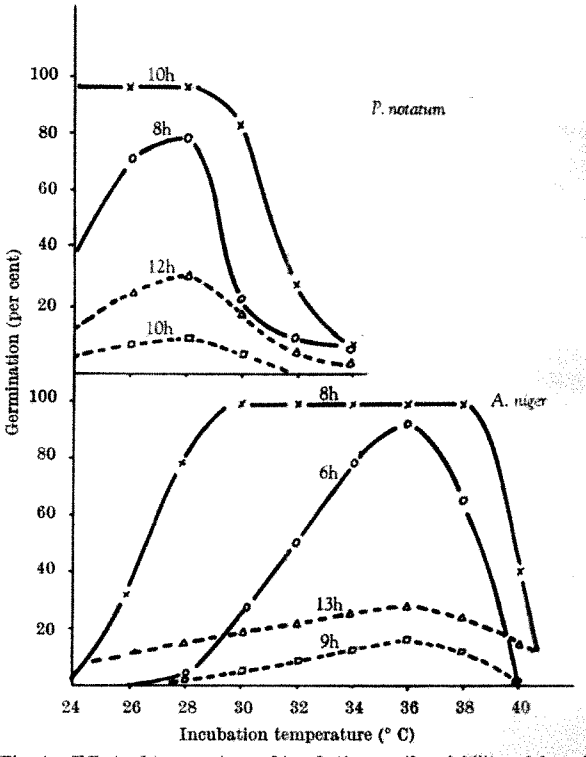

Fig. 1. Effect of temperature of incubation on the viability of fungal spores before and after treatment with 1 per cent phenol. ——, Untreated; - - - -, treated *P. notatum* for 20 min and *A. niger* for 15 min. Times are incubation periods before counting

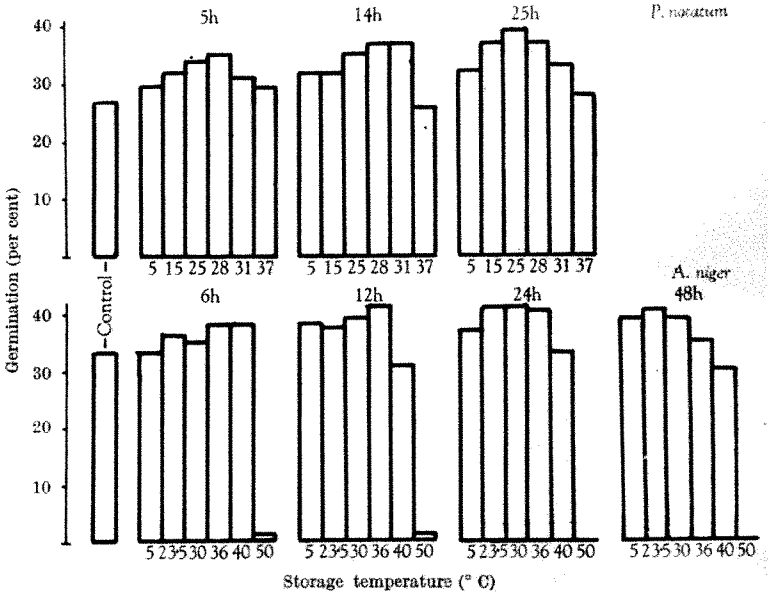

Fig. 2. Effect of duration and temperature of storage in water on the viability of fungal spores treated with 1 per cent phenol. *P. notatum* for 20 min and *A. niger* for 15 min. Times are duration of storage periods of spores in water after treatment with phenol, before aliquots of spore suspensions are added to double-strength Sabouraud medium and incubated at 28° for *P. notatum* and 36° for *A. niger* until maximum germination is obtained

be due to the utilization of residual energy for cellular repair and not for immediate spore germination, since water is an unsuitable growth medium. The transference of spores to culture medium may then permit such previously 'critically viable' spores to germinate. Desorption of the toxic agent from the spores during storage, as was suggested with triazine-treated *Neurospora sitophila*[8], seems an unlikely explanation since even after storage for 72 h supernatant fluids obtained by removal of spores by centrifuging had no ultra-violet absorption spectrum characteristic of phenol.

CYTOLOGY

Position of Labelled Chromatids in Diplochromosomes of Endo-reduplicated Cells after Uptake of Tritiated Thymidine

ENDO-REDUPLICATION as defined by Levan and Hauschka[1] consists of a microscopically non-visible duplication of the chromosomes within the cell nucleus leading to the formation of so-called 'diplochromosomes' in the following mitosis. Endo-reduplication has been reported to occur regularly, although rarely, in human tissues *in vitro*[2,3]. In a previous paper[3], we showed that in cultured human fibroblasts diplochromosomes originate by two separate and successive chromosome duplications. Diplochromosomes of endo-reduplicated cells which took up tritiated thymidine during the second chromosome replication show all four chromatids labelled in the following metaphase, whereas when tritiated thymidine was given during the first chromosome replication the label was restricted to but one chromatid of each of the two chromosomes forming a diplochromosome. These observations lead to the conclusion that the chromatids of diplochromosomes are, like chromatids of ordinary human chromosomes[4], composed of two sub-units which are distributed in a semi-conservative mode during chromosome duplications. The duration of one endo-reduplication cycle is in the range of two cycles of a diploid cell.

In the work recorded here we induced endo-reduplication with α-mercapto-ethanol[5] in order to examine the formation of diplochromosomes in a greater number of cells. In autoradiographic investigations using tritiated thymidine our attention was drawn to some irregularities in the duration of induced endo-reduplication and to a regular pattern of the position of newly replicated chromatid sub-units in diplochromosomes.

Cultures of peripheral blood cells from healthy persons were set up in the usual way[6] with α-mercapto-ethanol added at the beginning of culturing in a final concentration of 0·01 vol. per cent. After 3·5–4 days, tritiated thymidine (Radiochemical Centre, Amersham, sp. act. 7·2 c./mmole) was added in a concentration of 1 μc./ml. medium for a period of 12 h; the cultures were then washed twice in Gey's solution and fresh medium (made up with autologous serum) without tritiated thymidine and without mercapto-ethanol was added. Chromosome preparations were made 40 and 52 h after the end of treatment with tritiated thymidine. Colcemid (2 μg/ml.) was given 4 h previous to preparation. Kodak emulsion *NTB2* was used for autoradiography; radiation time was 14 days.

In cultures thus treated with mercapto-ethanol many metaphases of endo-reduplicated cells are found. The diplochromosomes of these cells are somewhat different from those occurring spontaneously in fibroblast cultures. In the latter the two chromosomes forming a diplochromosome are only weakly connected at the centromeric regions and usually lie a small distance apart, probably due to the spreading process during preparation. The chromosome pairs of diplochromosomes in mercapto-ethanol treated blood cultures are more closely attached. No direct connexion, however, is visible between the centromere of the two chromosomes.

The labelling patterns of diplochromosomes in preparations made 40 and 52 h after the end of a 12-h treatment with tritiated thymidine indicate that most endo-reduplicated cells are labelled during first synthesis and a few even during second synthesis, that is the synthesis preceding mitosis. Diploid cells in the same preparations show chromatid labelling, indicating that they are in second or third mitosis after uptake of tritiated thymidine. Thus diplochromosome formation induced by mercapto-ethanol may take longer than two cycles of a diploid cell.

In diplochromosomes of endo-reduplicated cells which took up tritiated thymidine during first replication and therefore have one chromatid of each of the two paired chromosomes labelled, quite frequently the two outward situated chromatids are the labelled ones (Fig. 1). Exceptions from this behaviour are rare, mostly when chromatids or their arms seem to be bent and folded around each other or where true chromatid exchanges may have occurred. The relatively small size of human chromosomes and the rather poorly preserved morphology of diplochromosomes after mercapto-ethanol treatment have allowed no detailed analysis of frequency and type of chromatid exchanges so far.

The characteristic outward position of labelled chromatids in diplochromosomes escaped our attention when we examined spontaneous endo-reduplication in fibroblast cultures[3], since in this case diplochromosomes are seen with the labelled chromatids also in other positions. However, a count of 60 diplochromosomes from spontaneous endo-reduplicated fibroblasts labelled during first synthesis revealed that more than half the diplochromosomes show both the labelled chromatids in the outward position;

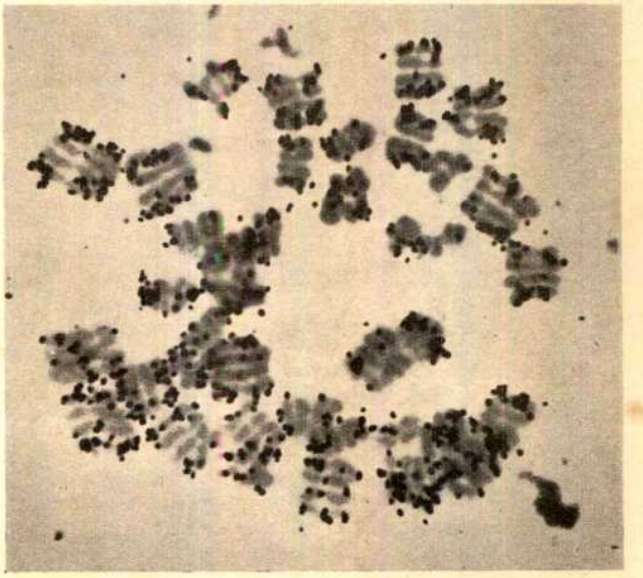

Fig. 1. Autoradiography of a metaphase of an endo-reduplicated cell which took up tritiated thymidine during first DNA-synthesis. In most diplochromosomes the grains are restricted to the two outward positioned chromatids (× 1,200)

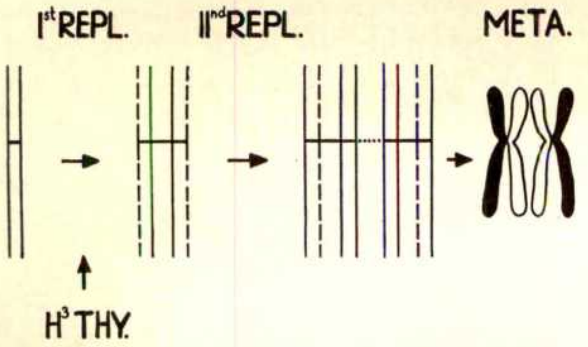

Fig. 2. Schematic representation of position of sub-units in endo-reduplication. Tritiated thymidine added during first replication. Broken lines: labelled sub-units, labelled chromatids of diplochromosomes in metaphase (indicated in black) in outward position

the rest show in most cases one labelled chromatid outward and one inward and only very rarely are both inward chromatids labelled. If the labelled chromatids are distributed at random, in 25 per cent of diplochromosomes both should lie outward, in 50 per cent one inward and one outward, and in the other 25 per cent both should lie inward. The actually observed preference of the outward position of both labelled chromatids indicates that in spontaneous endo-reduplication also this is the original position which can only be disturbed by secondary movements of the chromosomes such as, for example, those caused by spreading in the course of preparation.

The sub-units which were newly synthesized with first replication are seen on second replication to be old sub-units of the outward situated chromatids (Fig. 2). There must be a certain direction in replication bringing newly synthesized sub-units into a defined position. They are also forced to move outward, that is in a direction opposite to that of the centromeric connexion of the original sub-units, when the next replication takes place. It is possible that the centromere has some influence on the position of newly synthesized sub-units. Also chromosomal proteins or 'linkers' connecting DNA strands or segments[7,8] could serve as a frame which allows segregation and replication of DNA molecules only in a given direction.

Note added in proof. After this communication had been submitted for publication, K. Walen (*Genetics*, **51**, 915; 1965) reported observations on the position of chromatids in endo-reduplicated cells of *Potorous tridactylis*, quite similar to our findings in human material.

Chromosome Abnormalities in Lymphatic Leukaemia in Cattle

The specific change in the chromosome complement reported by Gustavsson and Rockborn[1] in three cases of overt leukaemia in cattle is extremely interesting, but care should be taken in identifying the chromosome changes with the neoplastic condition. This may not have been the intention of the authors, but it is an important distinction for the following reasons:

(1) We have studied the chromosomes in more than twenty cases of lymphosarcoma (lymphatic leukaemia) in cattle, nine of which have been reported[2], and in only two cases, one described by us[2] and the other by Basrur *et al.*[3], have similar chromosomal changes been observed; namely, an additional submetacentric chromosome and a minute chromosome in place of one of the small acrocentric chromosomes.

(2) In the three cases reported by Gustavsson and Rockborn, all the mitoses from the peripheral blood leucocyte cultures showed the same chromosomal change. This would be unusual if the chromosomal change was associated with the neoplasia, because in our experience, even when chromosomal changes occur in the peripheral blood leucocytes of cattle with lymphosarcoma, a number of cells with apparently normal karyotypes are always present in cultures to which phytohaemagglutinin has been added.

(3) The finding of the same chromosomal change in cells from the bone marrow and kidney of the foetus of one of the cows and in peripheral blood leucocytes of the three cows would seem to offer further evidence that the chromosomal change was generalized and not confined to the cells of the lymphatic system or associated with the neoplastic condition. Chromosomal analyses of other cells from the cows, for example, bone marrow cells and fibroblasts, in addition to the peripheral blood leucocytes, would have helped to throw light on the significance of the change in the chromosome complement and on the possibility that it may have been inherited.

GENETICS

Periclinal Nature of the Ivy-leaf Sport in Potatoes

The use of X-ray treatment[1] can produce from periclinal chimeras of potatoes (*Solanum tuberosum* L.) a small frequency (about 5–10 per cent) of plants which have at least the two outer layers at the growing point (L_1 and

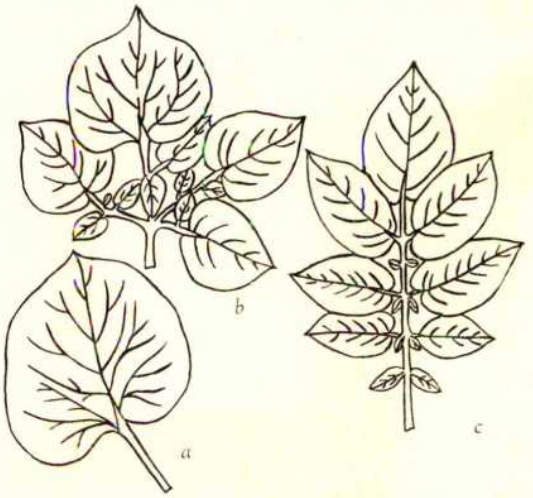

Fig. 1. *a* and *b*, Leaves of Ivy-leaf 'Doon Star' sport; lower, simple, and upper, compound respectively; *c*, pinnate leaf on shoot of plant produced by X-ray treatment of the sport. (All × *c*. 1/3)

L_2) with the constitution of L_1 in the chimera. Sports for large changes in leaf shape[2] probably always have a mutated L_2 and in many cases the mutation is also in L_3. Such sports cannot therefore be shown to be chimeras by either breeding or eye-excision experiments; this explains why the ivy-leaf sport (Figs. 1*a* and *b*) has not previously been shown to be a chimera.

Eye-excision experiments with the ivy-leaf sport of the variety 'Doon Star' produced only plants with ivy leaves. The cross of ivy-leaf 'Doon Star' × 'Ulster Prince' gave a family in which there were 23 seedlings with ivy leaves and 28 with normal pinnate leaves. In crosses of normal 'Doon Star' no seedlings with ivy leaves are produced. There is thus no doubt that ivy-leaf 'Doon Star' results from a dominant mutation for leaf shape in L_2.

Ten rose (apical) ends of tubers of ivy-leaf 'Doon Star' were given an X-ray dosage of 3,500 r., and all ten ends produced plants. On two of these plants shoots with normal pinnate leaves (Fig. 1*c*), in addition to shoots with ivy leaves, were found. It thus appears that L_1 in the ivy-leaf sport, like L_1 in the docken-(entire-) leaf 'Majestic' sport[3], has the unchanged genotype for normal, pinnate leaves.

PSYCHIATRY

Correlation between Scores for Dementia and Counts of 'Senile Plaques' in Cerebral Grey Matter of Elderly Subjects

Small, discrete masses of argyrophilic particles, with a mean diameter of 50–60μ, were first seen in the cerebral cortex by Blocq and Marinesco[1] and named "senile plaques" by Simchowicz[2], who discovered large numbers of these lesions in cases of senile dementia. Since they may be present in the normal old person[3] and no close relationship between intensity of plaque formation and clinical changes was found by some workers[4], their relevance for senile dementia—the extreme form of intellectual decay of old age—has often been called into question. More recently Corsellis[5] has demonstrated a reasonably good correlation between clinical diagnosis and neuropathological changes in post-mortem studies of aged mental hospital patients. But the nature and extent of the relationship between plaque formation and mental deterioration in old age remained uncertain. An attempt has been made to shed further light on this problem by enquiries in a series of patients, aged 60 years and more, admitted with psychiatric or physical illness to mental and geriatric hospitals and subsequently studied at post-mortem. The aim was to carry out a quantitative assessment of the severity of dementia in individual subjects during life and to ascertain whether this bore any relationship with mean plaque counts in cerebral grey matter. At this stage of the enquiry cases with gross cerebrovascular lesions were excluded as there was no available technique for making a quantitative estimate of their extent. The degree of dementia was expressed in quantitative form by carrying out the two following assessments.

(1) Since dements show an increasing range and number of defects as their disorder progresses, a list of defects was drawn up with special emphasis on those involving everyday habits and skills. At assessment, the patient's current ability with regard to each item on the list was ascertained, and a positive score of 1 given for each item present. The sum of scores for the individual defects gave a 'dementia score' which might lie anywhere from 0 (indicating absence of dementia) to +28 (indicating very severe dementia).

(2) Simple psychological tests were given which had been previously shown to differentiate groups of demented and non-demented aged persons[6,7]. Scores were allocated for correct performance in these tests, the summed scores lying between 0 and +37. In this case the scoring was in the opposite direction.

These two assessment have been repeated at six-monthly intervals on survivors.

In the neuropathological investigation, sections were taken from the same areas of the frontal, parietal, temporal and occipital lobes of each cerebral hemisphere and stained by the Von Braunmühl method. Plaque counts were carried out in each of 60 low-power fields chosen at random from these sections by one of us (B. T.) who had no knowledge of the dementia or test scores. Product moment correlation coefficients were computed between the scores for dementia and psychological test performance recorded during life, and the mean plaque count estimated in each of 37 patients.

Item	Coefficient of correlation	Significance
Age	+0 184	N.S.
Dementia score	+0 777	V.H.S. $P < 0{\cdot}01$
Test score	−0 4734	V H.S. $P < 0$ 01

In Fig. 1, the mean plaque count has been plotted against dementia score. It will be seen that there is an approximately linear correlation between them. Plaque distribution was on the whole remarkably uniform. The significance of variations in the density of plaque distribution is under examination. Although the distinction between demented and non-demented subjects appears in clinical practice to be relatively sharp, the neuropathological difference between them would seem, in the light of this study to be a quantitative rather than a qualitative one. Thus, if we take a cut-off line at a mean plaque count of ten, 23 of the 24 subjects with a mean count below this figure had a dementia score of less than ten, while only two out of thirteen subjects with a higher mean count had a dementia score of less than ten. Dementia was present in a clinically obvious form in all subjects whose score exceeded approximately eight to nine, and the majority of those with clear-cur dementia are therefore placed to the right of the cut-off line (mean plaque count, 10) while nearly all of those showing no deterioration clinically were to the left of the line. In the only striking example of a discrepancy between mean plaque count (5) and dementia score (17), the neuropathological picture was in certain respects an unusual one, differing from that of the remaining cases with a dementia score of more than ten. In the latter group, the appearances conformed closely with those described in cases of senile dementia. The overlap in respect of plaque counts between those with low and those with high dementia scores is therefore small. It may arise from the margin of error attaching to the technique for estimating mean plaque

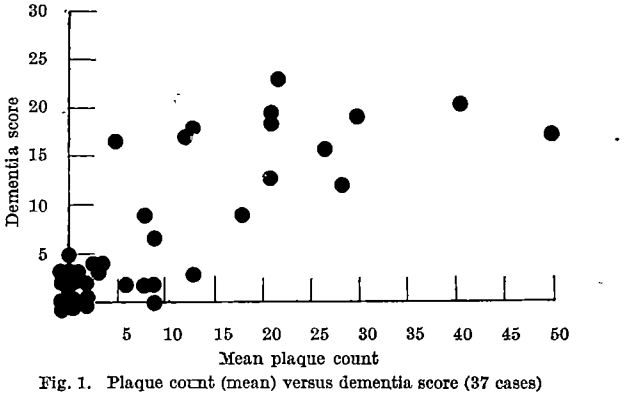

Fig. 1. Plaque count (mean) versus dementia score (37 cases)

counts, or of measuring dementia, from individual variation in respect of threshold for mean plaque count beyond which dementia becomes manifest, or more than one of these factors. It seems unlikely that the accumulation of plaques in large numbers could have been a preterminal phenomenon since several cases dying of carcinomatous metastases had very low plaque counts.

The following tentative conclusions may be drawn from the findings:

(1) Far from plaques being irrelevant for the pathology of old-age mental disorder, the density of plaque formation in the brain proves to be highly correlated with quantitative measures of intellectual and personality deterioration in aged subjects.

(2) The establishment of a valid measure of cerebral damage in one group of organic psychoses opens up the possibility of defining and measuring the psychological defects that show the best correlation with measures of cerebral damage.

(3) Senile dements have a markedly reduced expectation of life[8]. As the brain is an organ with a fixed cell population and such organs have long been known to be particularly liable to the changes of senescence, the facts suggest that senile plaque formation and related processes may also deserve investigation with the aid of more precise techniques than those employed in this study, for their possible relevance to the problems of ageing in man.

PSYCHOLOGY

Tranquillizers in Pregnancy and Behavioural Effects on the Offspring

In 1963 we published the third[1] in a series of reports[2,3] concerned with the administration of tranquillizers to gravid rats and their postnatal effects on the offspring. The data of this last report[1] indicated that meprobamate and not reserpine or chlorpromazine resulted in significant deficits in learning a Lashley III maze. This report generated much editorial comment[4,5] and additional experimental findings[6,7].

I wish to comment on these last two reports[6,7], not because they failed to replicate our findings but rather because their alterations in procedure implicate important and significant methodological questions concerning this area of research. Kletzkin *et al.*[6] administered meprobamate at a dosage of 20 mg/kg as compared to 60 mg/kg/day reported by Werboff and Kesner[1]. Furthermore, they[6] stated that the drug was injected for four days of gestation on days 5–9, 10–14, or 14–18 (these represent five days). Thus, the total dosage of meprobamate administered was 240 mg/kg in Werboff and Kesner's[1] experiment and either 80 or 100 mg/kg in the report by Kletzkin *et al.*[6]. Their inability to find differences between meprobamate-treated and control offspring in either body-weight, activity on the inclined plane, activity and emotionality on the open-field, and learning ability on the Lashley III maze could readily be explained by these differences in levels of dosage administered. These discrepancies then suggest the need for more detailed analysis of the dose-response characteristics of pregnant animals to meprobamate administration.

Hoffeld and Webster[7], in a more complete replication, compared the effects of meprobamate, reserpine, chlorpromazine, or water on body-weight, learning a Lashley III maze and a conditioned avoidance problem. The major contention of these authors is that our previous report failed to demonstrate effects related to the stage of pregnancy in which the drugs were administered. Stage-dependent results were found only in neonatal mortality[3]. The fact that no consistent stage-dependent results occurred on several unrelated measures[1-3] of maturation and behaviour requires that a more critical evaluation be made of the methodology of the Hoffeld and Webster[7] report. Two factors are immediately apparent. These authors purchased their animals already pregnant and thus such animals probably experienced severe stress from shipping in the early stages of pregnancy; secondly, the offspring were colony-housed from weaning at 21–80 days of age. During this time, they experienced whatever stresses are concomitant to a populated colony cage, and they did not experience the handling and testing on the battery of behavioural measures used by Werboff *et al.*[2,3]. Thus, the Hoffeld and Webster[7] animals had a variety of other prenatal and postnatal conditions which could easily have masked and altered the effects of the particular drugs administered in pregnancy on the behaviour of the offspring.

Hoffeld and Webster[7] deal specifically and critically with the Lashley III data from the Werboff and Kesner[1] report. It should be pointed out that Hoffeld and Webster[7] misquote these findings[1]: only meprobamate and not reserpine was found to produce learning deficits. Furthermore, Hoffeld and Webster[7] state that a comparison of the absolute values of the trials to criterion measure of control groups in various reports are of special interest. Werboff and Kesner[1] reported that the control group required 9·5 trials to criterion as compared to Hoffeld and Webster's[7] 14·2 trials to criterion. These authors then refer to a previous report of Werboff, Havlena and Sikov[8] in which prenatal irradiation was administered with a combined control group requiring 13·1 trials to criterion. The fact that the data from the control group of this investigation[8] are more in keeping with the data of Hoffeld and Webster[7] is noteworthy. The pregnant animals in this work[8] had to be carted several blocks to be irradiated under a variety of weather conditions. Thus, they may have experienced the same kind of 'shipping' stress received by the Hoffeld and Webster[7] animals, which may explain the differences and similarities between the scores of the various control groups on the Lashley III maze.

In spite of the fact that it is difficult to replicate conditions exactly from one experiment to another, certain important methodological variables have been suggested that may explain the discrepancies noted and that require further experimental elaboration. These are the questions of dose-response characteristics of pregnant animals to various drugs, and the effects of compounding additional prenatal and postnatal stresses on subsequent behavioural development. If these discrepancies lead us to uncover new data and new relations between critical variables, then our efforts would be rewarded.

This work was supported in part by grant *HD*-01019 from the U.S. National Institute of Child Health and Development.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, January 3

PLASTICS INSTITUTE (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p m —Mr. J. E. Proctor: Young People's Lecture.

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 3 p.m.—Sir Dudley Stamp, C.B.E.: "Philatelic Cartography".

INSTITUTION OF MECHANICAL ENGINEERS, MEDICAL ENGINEERING WORKING PARTY (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Informal Discussion on "Human Co-ordination and Engineering Control".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. A. P. Prosser: "The Chemistry of Mineral Processing".

Tuesday, January 4

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Earthworks—Are Present Specifications and Construction Plant the Most Suitable for the Soil and Climate Conditions in the British Isles", introduced by Mr. S. Rodin.

INSTITUTION OF ELECTRICAL ENGINEERS, CONTROL AND AUTOMATION DIVISION (at Savoy Place, London, W.C.2), at 5.30 p m.—Mr. E. G. C. Burt. "Satellite Control".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. D. L. Croom: "Naturally Occurring Thermal Radiation in the Range 1–10 Gc/s"; Mr. E. Denison and Mr. G. L. Rogers: "Aerial Noise Temperature at 5,650 Mc/s".

INSTITUTION OF MECHANICAL ENGINEERS, MANUFACTURE AND MANAGEMENT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Accountancy as a Service to Engineering Management".

Wednesday, January 5

OPERATIONAL RESEARCH SOCIETY (at the Royal Aeronautical Society, 4 Hamilton Place, London, W.1), at 4.30 p.m.—Prof. D. V. Lindley: "Bayesian Robustness".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p m.—Discussion on "Operating Experience with Deck Machinery" opened by Capt. W. S. C. Jenks, R.N., and Capt. D. Campbell, R.N.

ROYAL MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. John R. Baker, F.R.S.: "Experiments on the Function of the Eye in Light Microscopy" (Presidential Address).

Thursday, January 6

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S W.1), at 5.30 p.m.—Informal Discussion on "How Can Research Help Construction Methods", introduced by Mr. R. S. Taylor.

INSTITUTION OF MECHANICAL ENGINEERS, NUCLEAR ENERGY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Marine Reactor".

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 17 Belgrave Square, London, S.W.1), at 7 p m.—Mr. R. S. Sharpe: "Current Research in Non-Destructive Testing".

SOCIETY OF COSMETIC CHEMISTS OF GREAT BRITAIN (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7 30 p.m.—Mr. C. Freeman: "The Economics of Research".

Friday, January 7

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p m.—Discussion on "Tracking of Insulation" opened by Dr. A. G Day, Mr. P. J. Jackson and Mr. A. W. Stannett.

Monday, January 10

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"Taurus and Tibesti" (colour films of recent expeditions).

SOCIETY OF CHEMICAL INDUSTRY, COLLOID AND SURFACE CHEMISTRY GROUP (joint meeting with the London Section of the Oil and Colour Chemists' Association, at 14 Belgrave Square, London, S.W 1), at 6.30 p.m.—Mrs. S. M. Rybicka and Mr. A. F. Sherwood. "Surface Properties of Titanium Dioxide Pigments".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

TECHNICIAN or SENIOR TECHNICIAN IN THE DEPARTMENT OF MICROBIOLOGY for duties which will include assisting with research and taking charge of the preparation of class material—Prof. D. E Hughes, Department of Microbiology, University College of South Wales and Monmouthshire, Cathay's Park, Cardiff (January 7).

SENIOR LECTURER (with an honours degree and prepared to teach the subject to final B.Sc. (Applied Chemistry) and A P.I standard, and preferably appropriate industrial and/or research experience) IN THE CHEMISTRY AND TECHNOLOGY OF HIGH POLYMERS—The Principal, Rutherford College of Technology, Ellison Place, Newcastle upon Tyne, 1 (January 8).

UNIVERSITY LECTURER IN ANCIENT PHILOSOPHY—The Secretary of Faculties, University Registry, Oxford (January 8).

GRADUATE (with at least an upper second-class honours degree in botany, agricultural botany or plant physiology) to carry out individual research on the biology of perennial grass weeds in arable land—The Secretary, A.R.C. Weed Research Organization, Begbroke Hill, Kidlington, Oxford (January 10).

LECTURER or ASSISTANT LECTURER (with a special interest in one or more of the following: (*a*) economic geography; (*b*) planning; (*c*) a region other than Western Europe or the Americas) IN THE DEPARTMENT OF GEOGRAPHY—The Deputy Secretary, The University, Southampton (January 10).

ASSISTANT LECTURERS (2) IN THE DEPARTMENT OF PSYCHOLOGY—The Registrar, University College of North Wales, Bangor, North Wales (January 13).

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER (with an honours degree (or a diploma in technology) in entomology, engineering, botany or chemistry, and preferably some tropical experience) to spend periods overseas undertaking original investigations into problems associated with the handling and storage of foodstuffs in tropical climates, to evolve methods of improving quality and reducing losses, and to assist in the training of local personnel—The Director, Ministry of Overseas Development, Tropical Stored Products Centre, London Road, Slough, Bucks, quoting Ref. V/I (January 14).

ASSISTANT LECTURER (preferably with special interests in the scientific aspects of geography, for example, biogeography or climatology) IN GEOGRAPHY—The Registrar, The University, Manchester, 13, quoting Ref. 226/65 (January 15).

ASSISTANT LECTURERS, LECTURERS OR SENIOR LECTURERS IN THE DEPARTMENT OF APPLIED MATHEMATICS—The Registrar, The University, Sheffield (January 15).

DEMONSTRATOR/SENIOR DEMONSTRATOR IN THE SCHOOL OF PHYSICS—The Registrar, The University, Newcastle upon Tyne 2 (January 15).

LECTURERS or ASSISTANT LECTURERS (with special interests and qualifications in one of the following fields: experimental psychology; social psychology; personality and individual differences; psychometrics) in the Department of Psychology—The Deputy Secretary, The University, Southampton (January 15)

RESEARCH FELLOW or SENIOR RESEARCH FELLOW IN APPLIED MATHEMATICS—The Registrar, University of Queensland, Brisbane, Australia (January 15).

DEPUTY LIBRARIAN (honours graduate)—The Librarian, The University, Keele, Staffs (January 17).

CHAIR OF PHYSICAL CHEMISTRY—The Registrar, The University, Sheffield (January 22).

SENIOR LECTURER IN THE DEPARTMENT OF PATHOLOGY—The Registrar, The University, Sheffield (January 22).

LECTURER/SENIOR LECTURER IN VETERINARY VIROLOGY IN THE DEPARTMENT OF VETERINARY PATHOLOGY AND BACTERIOLOGY, University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 28).

LECTURER or SENIOR LECTURER IN THE DEPARTMENT OF PURE MATHEMATICS AND MATHEMATICAL STATISTICS—The Registrar, University College of South Wales and Monmouthshire, Cathay's Park, Cardiff (January 29)

RESEARCH SCIENTIST or SENIOR RESEARCH SCIENTIST (with a Ph.D. degree in an appropriate field or postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability) TO THE LEATHER RESEARCH SECTION OF THE DIVISION OF PROTEIN CHEMISTRY, Commonwealth Scientific and Industrial Research Organization, Parkville, Melbourne, Australia—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 quoting Appointment No. 462/244 (January 29).

ASSISTANT or ASSOCIATE PROFESSORS (with research experience in biochemistry, plant physiology or experimental biology) IN BIOCHEMISTRY AND BIOLOGY—Head of the Bioscience Department, Brock University, St. Catharines, Ontario, Canada (January 31).

CHAIR OF STATISTICS—The Secretary, The University, Aberdeen (January 31)

LECTURER IN THE SCHOOL OF SOCIOLOGY (Seconded to the Faculty of Medicine), University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31)

LECTURER (with a good honours degree in engineering or an equivalent qualification, and preferably some industrial experience) IN THE STRENGTH OF MATERIALS SECTION OF THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, University of Strathclyde, George Street, Glasgow, C 1 (January 31).

READER IN EXPERIMENTAL PHYSICS AT QUEEN MARY COLLEGE—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 31).

SENIOR LECTURER/LECTURER IN BIOCHEMISTRY at the University of Adelaide, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, January 31)

TECHNICAL ASSISTANT IN THE DEPARTMENT OF PSYCHOLOGY, Rhodes University, Grahamstown, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W.1 (South Africa and London, January 31).

LECTURER (preferably with experience in experimental fields of zoology) IN THE DEPARTMENT OF ZOOLOGY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 1)

SENIOR LECTURER/LECTURER IN DAIRY HUSBANDRY at Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; or the Registrar of the University (New Zealand and London, February 3)

LECTURER (preferably theoretical physicist with experience in crystal or solid state physics) IN PHYSICS at Queen's College, Dundee—The Secretary, University of St Andrews, Queen's College, Dundee, Scotland (February 12).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN PHYSICS, CHEMISTRY, BIOCHEMISTRY, ENGINEERING, METALLURGY AND PHARMACOLOGY, OR ANY RELATED SUBJECTS—The Registrar, The University, Liverpool, quoting Ref. CV/359 (February 14).

LECTURER/SENIOR LECTURER (with a degree in civil or agricultural engineering with experience and interests in the field of soil and water engineering) IN AGRICULTURAL ENGINEERING (SOIL AND WATER) at Lincoln College, University of Canterbury, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, February 14).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (preferably with a Ph.D. degree or equivalent research experience, and below the age of 30) IN APPLIED MATHEMATICS, BIOCHEMISTRY, CHEMISTRY, ENGINEERING, PHARMACOLOGY, OR PHYSICS—The Registrar, University of Strathclyde, George Street, Glasgow, C.1 (February 28).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (with a Ph.D. degree or equivalent research experience, and preferably below the age of 30. IN CHEMISTRY, CHEMICAL ENGINEERING, ENGINEERING SCIENCE AND PHYSICS—The Academic Registrar, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (February 28).

ASSISTANT or ASSOCIATE PROFESSORS (with a Ph.D. degree; special consideration for one position will be given to candidates with research interests in theoretical physics) IN THE DEPARTMENT OF PHYSICS—The University of Victoria, Victoria, B.C., Canada.

BACTERIOLOGIST (with at least three years' experience in bacteriology) to work as Assistant to Dr. E. S. Anderson, Director of the Enteric Reference Laboratory, Central Public Health Laboratory, Colindale Avenue, London, N.W.9—The Secretary, Public Health Laboratory Service Board, 24 Park Crescent, London, W.1.

BIOCHEMIST (preferably with experience with chromatographic and electrophoretic techniques) to join a team studying aspects of copper and magnesium metabolism in animals—The Secretary, Animal Diseases Research Association, Moredun Institute, Gilmerton, Edinburgh, 9, Scotland.

BOTANIST (morphology, anatomy, morphogenesis) IN THE BIOLOGY DEPARTMENT—Prof. E. Gorham, University of Alberta, Edmonton, Alberta, Canada.

CHAIR OF THEORETICAL ASTRONOMY—The Registrar and Secretary, The University of Sussex, Stanmer House, Stanmer, Brighton, Sussex, marking envelope "Confidential".

ELECTRONIC TECHNICIAN (Senior or Technician Grade according to experience) FOR THE DEVELOPMENT, CONSTRUCTION AND MAINTENANCE WORK IN THE RADIOTHERAPY, PHYSICS AND MEDICAL ELECTRONICS DEPARTMENTS—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. No PT/999.

GEOLOGIST (male, national of the United Kingdom or the Republic of Ireland, with a first- or good second-class honours degree in geology, preferably with experience of geological mapping of metamorphic terrain) IN MALAWI, to undertake geological mapping, geochemical surveys, investigation of mineral deposits and possible water supply investigations—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 218/134/02.

GRADUATE RESEARCH ASSISTANT for work on serology of tuberculosis including fluorescent antibody techniques—The Secretary, Harefield Hospital, Harefield, Middlesex.

GRADUATE RESEARCH ASSISTANT (preferably with an honours degree) for biochemical studies in muscle disease—Dr. B. P. Hughes, Institute of Neurology, The National Hospital, Queen Square, London, W.C.1.

HISTOPATHOLOGIST (with either a veterinary or medical qualification); and a TOXICOLOGIST or PHARMACOLOGIST (recent graduate in pharmacology, pharmacy or zoology) IN THE APPLIED PHARMACOLOGY DIVISION, for work concerned primarily with the pathology and toxicology of drug-induced lesions in experimental animals—The Personnel Manager, Arthur D. Little, Ltd., Inveresk Gate, Musselburgh, Midlothian, Scotland.

LECTURER and an ASSISTANT LECTURER IN INORGANIC CHEMISTRY—The Registrar, Hatfield College of Technology, Hatfield, Herts.

LECTURER IN BIOCHEMISTRY and a LECTURER IN MICROBIOLOGY—The Registrar, Hatfield College of Technology, Hatfield, Herts.

LECTURER IN BIOCHEMISTRY to teach the subject to the standard required for H.N.C. and H.N.D in applied biology and to assist in the development of biochemistry as part of the proposed M.I Biol. and Honours Degree courses —The Principal, South-East Essex College of Technology, Longbridge Road, Dagenham, Essex.

LECTURER (with a good honours degree and preferably postgraduate experience in neutron physics and/or health physics) IN PHYSICS IN THE DEPARTMENT OF PHYSICS AS APPLIED TO MEDICINE—The Secretary, Department of Physics as Applied to Medicine, Middlesex Hospital Medical School, London, W.1.

READER (with high academic qualifications, considerable research experience, and a particular interest in differential equations) IN MATHEMATICS (Ref. CST 65/129); and a LECTURER (with an honours degree or a diploma in technology; teaching, research or industrial experience; and a special interest in applications in electrical engineering) IN MATHEMATICS (Ref. CST 65/130) —The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting appropriate ref. number.

RESEARCH SCHOLAR for research on diffusion of hydrogen through metals —Dr. L. V. C. Rees, Chemistry Department, Imperial College, Imperial Institute Road, London, S.W.7.

RESEARCH STUDENT (suitably qualified British born chemist or physicist) to study the physical chemistry of solutions of oceanographic interest—Prof. Graham Hills, Chemistry Department, The University, Southampton.

SCIENCE RESEARCH COUNCIL POSTDOCTORAL ASSISTANTSHIP IN PHYSICAL ORGANIC CHEMISTRY—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

SENIOR LECTURER IN PHYSIOLOGY or PHARMACOLOGY—The Registrar, Hatfield College of Technology, Hatfield, Herts.

FOR PERIODS UP TO

1 hour
24 hours
7 days

The *Histokinette* stays on the job

Diagnostic reports to hand hours earlier than they would be with manual processing and in far greater numbers—the release of a valuable technician for other duties . . . these are the outstanding advantages of the Histokinette Automatic Tissue Processing machine. Once the Histokinette has been put into operation, it will *without supervision* go through the entire cycle of fixation, dehydration, impregnation in wax, or alternatively can be set up for the washing or staining of tissues. It can handle large numbers of specimens at the same time and while staff is off duty—speed up almost any technique by ensuring quicker and more thorough penetration by reagents.

A 24-hour clock is fitted as standard. Change over to 1 hour or 7 day cycles (*the latter of great value in double embedding and bone decalcification techniques*) is simple and rapid.

Histokinette special features include :—

- Up to 24 hours delayed start
- Double processing capacity
- One or more motor members and baskets
- Unbreakable tissue basket and containers

The Hendrey Histokinette is in general use at home and overseas

DEPLOYMENT OF MANPOWER IN SCIENCE AND TECHNOLOGY

THE Committee on Manpower Resources for Science and Technology, appointed in February by the Secretary of State for Education and Science and the Minister of Technology, with Sir Willis Jackson as chairman, has issued an introductory review of the scope and problems of policy for scientific and technological manpower*. The Committee has interpreted its responsibility of advising on manpower resources for science and technology as including the effective use of Britain's entire scientific and technological manpower, as well as the output of newly qualified individuals, in relation to the opportunities for employment. It believes that the deployment within the economy of existing scientists and technologists, and their utilization within any organization, demand as careful and urgent consideration as the continuing supply from Britain's educational system. Moreover, it considers that these problems should be studied against the background of the deployment of all highly qualified manpower.

Thus this authoritative Committee, at the outset, puts its finger on a key aspect of the manpower situation—the efficient use of trained manpower—which, although frequently noted, has seldom received more than passing discussion. That in itself should help to ensure that in future more attention is given to the question of supporting staff and that the triennial surveys of scientific and technological manpower will cover technicians. It is worth noting in this connexion that Sir Willis Jackson is also chairman of a committee set up in 1962 to consider the parameters of an enquiry into the employment of technicians in industry, the universities and the scientific and professional Civil Service. As a result of this enquiry, a new section on technicians and other technical supporting staff is being incorporated in the 1965 Manpower Survey, on the findings of which the Committee on Manpower Resources proposes to base the complete programme of its work. It might be added that another member of the Committee, Prof. C. A. Moser, is at present engaged in a survey of correlations between academic qualifications and performance in industry and that the Council for Scientific Policy has invited another member, Prof. F. S. Dainton, to study the flow from schools into places for science and technology offered in higher education.

The Committee is itself associated with this study and will be examining its results. To illustrate the representative character of the Committee, on which the Science Research Council, the University Grants Committee and the Ministry of Overseas Development, *inter alia*, have representatives, it should suffice to mention the names of Sir Leon Bagrit, Sir Peter Venables, Lord Brown of Machrihanish, and Prof. J. R. N. Stone. The Committee is basing its statistical surveys largely on the Census of Scientific and Technological Qualifications carried out in April 1961, and which is to be brought up to date by a recent enumeration in 1966, and on the triennial surveys, covering about 80 per cent of Britain's scientific manpower, which have been carried out by the Ministry of Labour since 1956. The latest survey, relating to January 1965, which is now being processed, has been designed to interlock with the more comprehensive enumerations of the 1961 and 1966 censuses of population. Data from this survey will enable the Committee to assess further the supply and demand for qualified manpower, both at present and in relation to employers' forecasts for 1968. In the light of this evidence and of other enquiries undertaken for purposes of general economic planning, the Committee proposes to attempt to determine how far present deficiencies within particular categories of scientific and technological manpower are due to overall quantitative shortages.

On the supply side, the Committee is looking to the statistics provided by the University Grants Committee, the Education Departments and the professional institutions. These statistics show the inflow of scientists and, when set against estimates of wastage of all kinds, will allow more accurate forward estimates of the stock of scientific manpower in Britain. The Committee points out, however, that an accurate assessment requires a comprehensive understanding of the relation between scientific and technological education on one hand, and employment on the other. This has profound implications for professional education and the number of places universities offer in particular disciplines, as well as in respect of the broad basis of scientific and professional education and the transfer between subjects, if not between disciplines. Employers, for example, in replying to questionnaires about future demand, often start with their own needs for specialized technologists and estimate the number of individuals who are likely to fill these posts from the disciplines listed.

The material the Committee is seeking to acquire has, therefore, implications for estimates of material needs in terms of disciplines and may call for some further thinking about the expansion of higher education. The Robbins Report based its estimates of the scale, and its concept of the pattern, of the future supply of qualified manpower from the educational system on a forecast of the numbers of boys and girls from the schools who would justify education at university level in subjects of their own choosing. Apart from the question (only superficially examined in the Report) of where that higher education would most appropriately be given, this suggests that, as counterpart to employers' forecasts of needs, an examination is desirable of factors affecting or determining the choice of subjects of study at school and in higher education. This also the Committee proposes to examine, together with the motives, character and abilities relevant to science and technology, and the extent to which they are encouraged or inhibited at each stage of education and training. The part played by imaginative teaching and up-to-date curricula in influencing choice for or against science and technology will also be examined.

These problems are already being investigated by the Schools Council in relation to England and Wales, and the Scottish Council for Research in Education is studying the validity of aptitude tests in selection for university places in relation to the subsequent performance of school

* Committee on Manpower Resources for Science and Technology. *A Review of the Scope and Problems of Scientific and Technological Manpower Policy*. Pp ii+17. (Cmnd. 2800.) (London: H.M.S.O., 1965.) 1*s* 6*d*. net.

leavers in higher education. The Committee also emphasizes its concern that sixth-form pupils taking science and mathematics should, in the course of their studies, come into contact with some teachers who have up-to-date technological backgrounds, and who have had experience and an interest in the application of science to practical ends. Few graduates in science and technology, however, enter the schools after industrial experience, and means should be devised to tap the knowledge and energies of those with recent and up-to-date experience in research and in industry. The problem is being examined by many bodies, but no proposals have so far been advanced which can make a measurable contribution in the schools themselves and, for the present, the Committee on Manpower Resources is content to emphasize the importance of this problem.

The Committee is not content, however, to accept the classification of scientific and technological manpower based on the disciplines in science and technology in which degrees are normally taken. It is sometimes necessary to supplement this education by a period of organized training in employment. This is not necessarily an unfavourable reflexion on the teaching given in institutions of higher education, particularly if the period of adaptation proves to be short. It is to the national advantage rather than otherwise that universities and other institutions should prepare individuals in the first instance broadly for their future responsibilities, so that they are adaptable to a wider variety of circumstances throughout their careers.

That a high proportion of vacancies available in industry are for types of technologists not produced solely by the educational system is not necessarily disturbing, provided it is remembered that, as the Manpower Committee points out, proportionately fewer young people capable of qualifying as scientists and technologists will start from the factory floor—this is especially so now that proportionately more young people go on from school to higher education. Nor does this trend merely affect the provision of part-time or full-time census for technicians and others in technical colleges; it accentuates the danger of too many students in institutions of higher education being orientated towards theory and research and away from design and production.

For this reason, the Committee on Manpower proposes to consider whether, and at what stage, the emphasis in courses in university or college of technology should be changed to match industrial needs more closely. This is partly a matter of communication between industry and higher education and, as a first stage, a working group has been appointed under Mr. G. S. Bosworth to study the problems involved in stating the requirements of industry in terms relevant to education. A member of the Committee, Mr. S. L. Bragg, is examining how far individuals from different academic disciplines are in practice interchanged or interchangeable. This could help to establish what kind of basic scientific or technological education would give the breadth of view needed to cope with new developments.

In this context the Committee welcomes the steps which are being taken, as the colleges of advanced technology become universities, to preserve and to develop those elements which have encouraged close contacts between educational courses and the practical requirements of employers. It particularly emphasizes the importance of preserving both the value of the sandwich course (above all, that which ensures an intimate contact between the educational course and industrial practice) and the opportunity for a candidate with an Ordinary National Certificate type of qualification to continue his education through a full-time sandwich course at university-level. It questions the validity of basing entry to certain advanced courses solely on academic criteria and proposes to examine this difficult problem further. There is some evidence that industry in general is not sufficiently aware of the role of the universities in providing postgraduate courses and that universities are not fully aware of the needs of employers. The Committee has accordingly recommended publication of a report by Mr. H. Arthur on an enquiry undertaken at the request of the Committee on Scientific Manpower in December 1963†.

This report has now been published and has been examined by the University Grants Committee, by the Postgraduate Training Awards Committee of the Science Research Council and by professional institutions concerned with technological education. Discussion of Mr. Arthur's findings has increased the awareness that industry must formulate better its needs for postgraduate courses if educational institutions are to cater for them effectively. However, this question of postgraduate courses may here be left with the note that the Committee on Manpower Resources supports the steps being taken by the Postgraduate Training Awards Committee of the Science Research Council to encourage the development of suitable courses at postgraduate level in technology. Advanced course studentships are being allocated more generously in relation to the demand for technology than for pure science subjects and the award system is being comprehensively reassessed so as to ensure that its resources are deployed as effectively as possible.

Apart from the question of technicians and other supporting staff and Prof. Moser's enquiry, other matters bearing on the more effective utilization of qualified manpower, which the Committee proposes to examine, include the optimum distribution of highly qualified people among private industry, the public sector and higher education; mobility between employments (including the need for adequate numbers of scientists and technologists in management); and courses in new technologies. The Committee proposes to keep in touch with the newly established Industrial Training Boards which have a major part to play in training technological manpower. It is also seeking to chart more fully the wastage of scientists and technologists whether by emigration or in other ways.

All this amounts to a considerable programme even when set against the research projects known to the Committee which are listed in an appendix. The Committee itself proposes to pay particular attention to the implications of long-term economic planning for policy for scientific and technological manpower; to identify motives and abilities relevant to science and technology and the factors governing the choice of a career in science or technology; to identify the main categories of scientists and technologists needed by industry and the relation of industry's needs to educational courses; to study the extent to which present resources of ability are fully mobilized, and problems of effective deployment and utilization of scientists at all stages in their career; to relate the interactions between scientists and technologists and their supporting staff; to investigate the migration of scientists and technologists internationally

† Department of Education and Science. *Enquiry into Longer-term Postgraduate Courses for Engineers and Technologists, 1964–65.* By H. Arthur. Pp. x+54. (London H.M.S.O., 1965.) 4*s.* 6*d.* net.

and within the economy. The present Manpower Report sets forth the broad approach of the Committee and the lines on which it is now thinking, and will doubtless provide in due course a yardstick against which its achievements will be measured.

Nevertheless, even at this early stage the Committee has identified some matters on which immediate action could, and should, be taken, and it concludes its report with five specific recommendations. First, universities should continue their efforts to provide more facilities for the increasing number of candidates in science and technology. Secondly, ways should be found to use imaginative and resourceful individuals with practical experience in research and development establishments and industry, to widen the scope of science and mathematics teaching in the schools and to demonstrate the challenge of careers in applied science and technology. (The Committee does not indicate where the responsibility for instigating this second recommendation should lie, but it clearly lies in part on itself, though more especially on the Department of Education and Science, and also on the professional institutions.)

Thirdly, the former colleges of advanced technology and the leading colleges of technology should be encouraged to maintain the resources devoted to sandwich courses, and to keep open opportunities for holders of national certificates to enter higher education in technology. Here, the major responsibility lies with the Department of Education and Science, as it does also for the fourth recommendation: that recommendation is for a closer partnership between the universities, colleges of technology, Government establishments and industry in promoting and conducting postgraduate courses in technology. At the same time, the Government should strengthen the preference given to supporting courses to which industry would send candidates with industrial training and experience, and which are well planned to prepare science graduates for technological employment. Industry should increasingly provide lecturers on particular technological subjects.

On the difficulties with regard to this last-mentioned point, some comments in Mr. Arthur's report are pertinent. To be really effective, he observes, staff of good calibre and experience are required, and this means they will be in senior positions and will be men that industry can least spare on full-time secondments. Firms and organizations are unwilling to contemplate full-time secondments for as long as a year, nor do the staff themselves wish to be absent for so long a period. Full-time secondment for a period from 3–6 months is more favourably regarded; it offers sufficient time to broaden the outlook of the staff seconded and will give useful experience to their deputies. The universities, however, seem only lukewarm to such full-time secondments: they feel that it takes an appreciable time for a man to settle down and become an effective member of the academic staff.

The universities would accordingly prefer the services of an industrialist on a part-time basis regularly over a period of several years. This arrangement involves considerable strain on the individuals concerned, but should be possible if the academic load is not too heavy and if the individual has the support of competent staff on the industrial side. A few universities have already made arrangements with large industrial organizations for the appointment of honorary readers or part-time or visiting professors and lecturers, and possibly the Committee on Manpower Resources could encourage the spread of this practice. It could also be helped by the growth of secondment of academic staff for periods of experience in industry. Here, however, the difficulties are more considerable and much may depend on how far the Department of Education and Science is able to assist universities and colleges of technology with the cost of industrial fellowships of this type, and also on the development of liaison generally between industry and the universities and colleges of technology.

The Committee's fifth, and final, recommendation, namely, that Industrial Training Boards should give particular attention to more graduate facilities within industry, is essentially a matter for the Minister of Labour. Here also, however, the Committee itself could act as a general co-ordinating authority as well as a central forum for considering the problems which arise. Its vision and energy will call for the firm support of other Ministers besides those to whom this report is presented to secure the necessary action based on the fuller understanding which the investigations it proposes should provide.

THE SCIENTIFIC ESTATE

The Scientific Estate

By Don K. Price. Pp. xi+323. (Cambridge, Mass.: The Belknap Press of Harvard University Press, 1965.) n.p.

THE SCIENTIFIC ESTATE, which is likely to become a major authority in the field of science and administration, represents an appreciation of the new and important part science is playing in government. It might be taken as another example of the development of the 'science of science', except for the fact that it is not written by a physical scientist but by a distinguished social scientist who has had a long experience in government and industry and is at present Dean of the Graduate School of Public Administration of Harvard University. It represents an attempt to fit scientific research into the framework of government and administration and, in a way, it has succeeded in doing this. But reading the book yields a very different picture; from what we know from other sources in the United States and in Britain, the picture presented of the relations of science to politics is an idealized one and still far removed from reality.

Prof. Price has chosen to treat science in the United States as one of the estates of the realm: "The four broad functions in government and public affairs—the scientific, the professional, the administrative and the political—are by no means sharply distinguished from one another even in theory, but fall along a gradation or spectrum within our political system. At one end of the spectrum, pure science is concerned with knowledge and truth; at the other end pure politics is concerned with power and action. But neither ever exists in its pure form. Every person, in his actual work, is concerned to some extent with all four functions. The laboratory scientist is probably interested in some professional association with his colleagues, in the administration of his laboratory, and in the support for his work that comes only from money or influence. At the other extreme, the Congressman or the President must be interested in the ways in which new knowledge affects his status and his purposes, and in which professional skills and administrative competence can support them" (p. 135). He is motivated not by any hostility to science but by the fear that scientists might use their specialized knowledge to determine policy and to pervert the proper functions of democratic control. To make his point, Prof. Price has to enter into a long historical discussion of the relations between science and government, particularly in the United States, but including much of the history of science in Britain with which he shows himself to be exceptionally well acquainted.

(Prof. Price, as might be expected, has been a Rhodes scholar at the University of Oxford.)

Ostensibly, the control of science in the United States is not so much the concern of the President or of the executive organs of state as of various congressional committees which are associated with different scientific programmes. The reference to congressional committees is assumed to guarantee control of scientific investigations and the policy arising from them, but that the control is really democratic cannot be uncritically accepted by anyone with more than superficial knowledge of how science is run in the United States; even an attentive reader of the book can see that the picture is unintentionally scarcely more than a 'cover story' for what actually goes on.

The picture presented is, in fact, one of very extensive administrative chaos because major considerations are necessarily left out. The enormous sums of money spent on science in the United States, for example, easily more than in the whole of the rest of the world put together, are not distributed according to any rational system but are due to the interplay, less of democratic than of military and economic considerations.

The underlying aim of the presentation here given of the scientific estate is to ensure that the scientist is 'on tap' but not 'on top'. But the scientist is at the same time a man and is recognized to have motives and interests of his own: "If we understand that the scientist and the engineer cannot be guided in their political actions entirely by what science teaches them, and that even when they think they are doing so they may be deceiving themselves and others, we are led to a realization that the fruit of the tree of knowledge is not always peace" (p. 142). The fundamental difficulty which Prof. Price never resolves is to work out a way in which people essentially ignorant of the facts of science can direct policy which more and more involves science. This applies equally to the United States and British systems.

The book will make difficult reading for a British reader unless he knows the United States very well, but the realities are easier to understand than the official theory which covers them. In various places Prof. Price realistically likens the administration of science to the feudal system where a number of rival barons are occupied in fighting against each other for the appropriations which would enlarge their prestige. They are kept in control, with varying success, by powerful agents of the President. The enormous sums spent on the policies on which they are based really speak for themselves. The underlying theme is war, of an objective or mechanical nature, or its equivalent in popular prestige, which is really war in another form, as applied to the Kennedy objective of landing men on the Moon by 1970. This is the objective of the aerospace agencies, for which a great effort is undertaken, equivalent to more than all that is spent on fundamental science in other fields, regardless of scientific opinion, but having the necessary public appeal and at the same time being extremely profitable to the firms involved, even to whole areas in which they operate for the time being.

In Chapter 4, "The Established Dissenters", Prof. Price shows how scientists themselves have used the prestige they have gained by their contributions to military success to attempt to influence policy directly, often in opposition to the policy laid down officially. Any logical plan for scientific expenditure can always be overridden in the military field because where victory or survival is at stake it is pointless to count the cost. Evidently this puts the direction of science as a by-product of the 'military-industrial complex' of President Eisenhower. But this is not developed in detail. His references to Oppenheimer are scanty and, among the established dissenters, the name of Linus Pauling does not appear in the index between 'Patronage' and 'Pearl Harbour'.

The book contains a fascinating account of the origins of successive administrative scientific bodies which have been set up to organize science in the United States since the time of Jefferson. How the United States ever came to be such a scientifically great power is not apparent. Evidently it was just as much an accident as the acquisition of the British Empire—in a fit of absence of mind. This is, however, very far from the whole truth. The principal policy has been to relegate basic science to the universities—all definite project research is paid for by the government and outside the ordinary funds of the university—and to entrust development contracts to leading industrial firms.

There have been from time to time various efforts at retrenchment but these have been quickly suppressed on account of the needs of recent wars, such as those of Korea and Vietnam. The basic principle is that universities cannot afford not to develop science to the utmost, but they do not wish to do this, mainly on the advice of the scientists themselves who are apt not to take the policies of their government as automatically perfect. In the process, the legislative forces are generally easily carried along on the basis of national security, containing communism, or showing that the United States has the biggest and most destructive weapons.

Prof. Price has chosen as an example the great post-War development of oceanography research: "Oceanography, for example, was to each of more than a dozen agencies an important means towards its particular purpose. But each agency, if left to itself, would have planned its research and development work in the way that would contribute to its own purposes, regardless of the interests of others. To make the programme into an effective whole, the Office of Science and Technology had to work with the agencies concerned. If possible it had to persuade each of them to include the appropriate share of the total programme in its budget, even though this meant that each had to undertake some work not directly relevant to its own purposes as it saw them and consequently that, in order to stay within its budget, it would have to cut out something that it would prefer not to do" (p. 246). But the central *raison d'être* of the oceanographic programme, though admittedly furthering the activities of the *Polaris* submarines, is hardly touched on.

The book is eminently readable but essentially of more interest to the administrator than to the scientist and carries valuable lessons for the comparatively cautious and unenterprising science in Britain, but, as can be seen from these comments, it leaves out as many important factors as it brings in.

J. D. Bernal

COMPENDIUM OF SPACE LORE

Sourcebook on the Space Sciences

By Samuel Glasstone. Pp. xviii+937. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1965.) 62*s*.

When the United States Government founded the National Aeronautics and Space Administration (N.A.S.A.) in 1958, the new organization was instructed not only to explore space but also to "provide for the widest practicable and appropriate dissemination of information concerning its activities". N.A.S.A. has faithfully performed this task by giving advance details of all projects and reporting the results of the experiments. To supplement these frequent Press releases and reports of current events, the Information Division of N.A.S.A. commissioned Dr. Samuel Glasstone to prepare a compendium of basic knowledge in the space sciences: this is the origin of the 937-page volume under review. N.A.S.A. holds the copyright, and the list of acknowledgments shows that no fewer than eighty-two individuals, most of them connected with N.A.S.A., gave their opinions of particular chapters in the book. Thus, although Dr. Glasstone is the author, *Sourcebook on the Space Sciences* must be regarded as bordering on an official N.A.S.A. publication:

the text and illustrations are both strongly orientated towards United States achievements. When we have made allowance for this bias, however, we are left with a book which it would be difficult to improve upon, except in minor details. The topics are well chosen, the treatment is accurate and assured, and the author is never guilty of introducing a needless fog of technical detail. The most pleasing features of the book are the clear and direct style of writing, the historical touches which so often illuminate descriptions of the present situation, and the author's courtesy in pausing to elucidate the origins of technical terms which in most books are flung at the reader in a daunting barrage.

The book begins with a historical review of astronautics and rocketry, from science fiction and twelfth-century Chinese rockets to the first actual launchings in 1957. Chapter 2 describes the basic properties of Earth-satellite orbits and space trajectories, while keeping clear of heavy mathematics. Chapter 3 is a thorough treatment of propulsion and power supplies, including an outline of the main United States launch vehicles. In Chapter 4, on guidance, tracking and telemetry, the section on tracking is deficient because it describes only those facilities supported by N.A.S.A. Chapter 5 is an account of the peaceful applications of satellites in meteorology, communications and navigation.

Chapters 6–12, which make up nearly two-thirds of the book, bring a change of emphasis, and are concerned with pure space science and astronomy. In Chapters 6 and 7, entitled "The Sun" and "The Solar System", respectively, the author steers a judicious course among the various controversial rocks on which the narrative might have been wrecked (for example, the origin of tektites—or of the solar system). Chapter 8 is a long and well-balanced survey of the Earth and its environment. Chapter 9 is devoted to the Moon, and again the controversial topics, such as the surface, figure and origin of the Moon, are discussed with such willingness to see both sides of the question that criticism is quite disarmed. In Chapters 10 and 11 we travel to the inner and outer planets, respectively, while Chapter 12 enjoys the comprehensive title "The Universe", and ranges from the minutiae of the Hertzsprung–Russell diagram to the starry-eyed speculations of cosmological theory. After these philosophical flights, there is a touch of bathos about the final chapter, "Man in Space", which might have had as its motto:

> The time has come, the Walrus said,
> To talk of many things,
> Of pressure suits and calcium loss,
> Of moons and Saturn's rings,
> Of waste disposal up aloft
> And whether LEMs* have wings.

This last chapter is certainly a useful reminder that although man may have his head among the stars, his feet are still in the gutter (if a misquotation from Oscar Wilde may be allowed to balance that from Lewis Carroll).

Besides being well written, the book is up to date and excellently printed, with very few misprints or minor Mistakes. In a book of such length, however, some errors have inevitably crept in. For example, in the map of Minitrack stations on p. 218, Winkfield has been translated from English soil to Dutch, and on p. 224 Canberra has slipped into Western Australia. The Sun seems to be rotating the wrong way on four diagrams (pp. 532–542), and, more serious, the derivation of the basic rocket equation on p. 171 is fallacious, even though it leads to the right answer.

The book carries good indexes of subjects and names, but there are no references or bibliography: a full bibliography would have been excessively lengthy, but at least there might have been a list of journals which normally publish papers on space science. Indeed, the title 'Sourcebook' is slightly misleading, since the book is not a collection of original papers. These are but minor flaws, however, in a masterly book which every student of space science will wish to acquire. Reviewers cannot even voice their standard complaint that the book is too expensive: for its price is less than a penny a page.

D. G. King-Hele

* LEMs, Lunar Excursion Modules.

NATO AND THE SOLAR SYSTEM

Solar System Radio Astronomy

Edited by Jules Aarons. (Lectures presented at the NATO Advanced Study Institute of the National Observatory of Athens, Cape Sounion, August 2–15, 1964.) Pp. xi+416. (New York: Plenum Press, 1965.) 17.50 dollars.

THIS expensive book is a series of lectures given at a summer school on the radio- and radar-astronomy of the solar system. Forty-three such schools were sponsored by NATO during 1964 at a cost of 650,000 dollars. No restrictions are placed on the form or organization of these schools, except that they take place in a country of the alliance; participation and financial support are not, however, limited to citizens of the NATO nations. In this case the country was Greece, and the Director of the Summer School was Prof. Michail Anastassiades of the University of Athens, who collaborated with Dr. Jules Aarons of the Air Force Cambridge Research Laboratories (U.S.A.) in organizing the programme. Their success is evident in *Solar System Radio Astronomy*: in many cases the lecturer was the acknowledged international authority on his subject. The students at the school were young scientists at the beginning of their research careers, and much opportunity for informal discussion was provided in the pleasant surroundings of Cape Sounion.

More than half the book is devoted to the radio emission from the Sun, both quiet and disturbed, and forms a useful summary of this immensely complicated subject, mainly from the point of view of the observer. Then follows a discussion by Hewish of the investigation of the far-out corona by the now-classical method of radio source occultation. This ends with a mention of the important subject of interplanetary scintillations, by means of which Hewish has detected many quasars.

The investigation of gaseous regions in the Solar System by radio and radar techniques, including sun radar, is discussed by von Eshleman. Since this chapter was written these methods have scored a major success in the measurement of the atmosphere and ionosphere of Mars by observing the occultation of the probe *Mariner* 4. This work was planned by a Jet Propulsion Laboratory–Stanford group. Propagation studies within the Solar System, either by ground-based radar or using probes as transmitters or transponders, will clearly continue to make important contributions; this lecture also includes a discussion of the Stanford electron density measurements of the *cis*-lunar region by harmonically related multi-frequency radar.

The rest of the book is devoted to the rapidly growing field of the radio- and radar-astronomy of the Moon and planets. Confronted with the volume and complication of the information now available, it is hard to recall that the first Venus echoes were observed as recently as 1961, and that the effective study of the planets by passive radio-astronomy is scarcely an older subject. A measure of the speed of advance in these fields is provided by the discoveries made since the summer of 1964 when the lectures were given, for example, the non-synchronous rotation of Mercury as detected by radar.

This is altogether an exciting book, reflecting the renewal of interest in the solar system, stimulated in part by the space age, but probably more by the new techniques of radio and radar. It will date less than do most conference proceedings, being the lectures of a summer school designed to be tutorial as well as topical.

J. H. Thomson

MAST CELLS

The Mast Cells

By Dr. Hans Selye. Pp. xxix + 498. (Washington, D.C.: Butterworth, Inc.; London: Butterworth and Co. (Publishers), Ltd., 1965.) 135*s*.

SIR ERNEST KENNAWAY once observed that "cancer research is tending to become buried under its own literature". Similar thoughts about the mast cell were evidently in the mind of Prof. Selye of Montreal when he set out to review, in *The Mast Cells*, an expanding literature already comprising some 2,500 titles. The treatment is novel—'a book within a book'. Each chapter and major sub-division opens in large type: collectively, these portions of the book form a running narrative, unencumbered by references, though legitimately coloured by the views and experience of the author. The remainder of the text, in smaller type, is made up of brisk, telegraphic abstracts of the pertinent literature. A numbered code guides the reader thence to a full bibliography. The final index is printed on tinted paper. Every aspect of the mast cell is dealt with. The result is superb.

There are two types of mast cell, both discovered by Paul Ehrlich early in his career. The first is the tissue mast cell which develops, dies and, as many believe, has its function, in the connective tissue. The second is the basophil (blood mast cell or mast leucocyte) the origin of which is in the bone marrow and the habitat of which is the peripheral blood. Both types of mast cell elaborate cytoplasmic granules which stain metachromatically with various basic dyes. They were named *Mastzellen* in the belief that their granules form under conditions of hypernutrition (*masten*, to fatten).

Sixty years after Ehrlich's discovery, Scandinavian workers gave to the mast cell its first plausible function. They were seeking a cellular location for the powerful anticoagulant, heparin, and found it in the metachromatic granules of the tissue mast cell. Fifteen years later it was shown, by us, in Scotland, that the mast cell is as rich in histamine as it is in heparin. This stimulated intensive investigation on the mode of action of the newly discovered histamine-liberators. There was more to come. American workers then demonstrated 5-hydroxytryptamine in the mast cells of mouse and rat. All these pharmacologically active agents are synthesized and stored within the mast cell. The mast granules are also curiously rich in protease and contain smaller amounts of other enzymes. Recent observations suggest that catecholamines may be present in certain types of mast cell. For long the mast cell lacked a function. Now it has too many. This is a baffling situation for the investigator: the newcomer, especially, looks for guidance.

Prof. Selye's book supplies his needs. There have been reviews in the past, of which, perhaps, Michels's brilliant chapter in Downey's *Haematology* (1938, and reprinted as part of a mast-cell symposium, *Ann. N.Y. Acad. Sci.*, 103, 491; 1963) remains outstanding. Specialized monographs are available on heparin, histamine, hyaluronic acid, histochemistry, mast cells and lymphocytes, mast cells and anaphylaxis, the basophil—there are many excellent shorter surveys. Selye has out-reviewed us all. For the moment the mast cell has been brought within the compass of the individual.

Armed with this lavish compendium the reader can see at a glance where knowledge is well advanced and where gaps remain. Short chapters on history, definition and terminology are followed by a long chapter on histology, including histochemistry. Embryology, a mere two pages, could already be profitably expanded by the inclusion of recent work by Burton (*Anat. Rec.*, 150, 265; 1964) and Combs, Lagunoff and Benditt (*J. Cell Biol.*, 25, 577; 1965). Likewise, the next section on comparative anatomy could usefully draw on the comprehensive survey by Grünberg and Kaiser (*Zbl. f. Veterinarm.*, 11, 729; 1964; 12, 18; 1965). The longest chapter, "Agents Affecting Mast Cells", includes a detailed account of Prof. Selye's own contribution to the mast-cell story: 'calciphylaxis' implies the deposition of calcium, often massive, around mast cells or their products in hypercalcaemic rats; 'calcergy' denotes a somewhat similar calcification in normal rats previously injected with certain metals. Calciphylaxis was itself the subject of a considerable monograph by Prof. Selye some three years ago. Excellent chapters then deal with the diseases of the mast-cell system, the mastocytoses and mast-cell dermatoses in man, and the mastocytomas in animals. The same thorough treatment leads through biochemistry and the blood basophil to theories. Here, though many points of view are considered, the reader will seek in vain for a hypothesis to cover all mast cells in all species.

Heparin can certainly be extracted chemically from mast cells, yet there is little to suggest a physiological release of heparin into the blood: in some quarters the mucopolysaccharide is now regarded more as a structural component of the granule than a potential secretion. Histamine is undoubtedly synthesized and stored in mast cells, and is easily released. However, one would question the statement (p. 366) that "virtually the whole histidine-decarboxylase activity of the body is concentrated in mast cells": even the specific enzyme (*p*H 6·5 and sole substrate, histidine) has a wider distribution. 5-hydroxytryptamine (serotonin) is restricted to the mast cells of mouse and rat. Calciphylaxis and calcergy have likewise as yet been demonstrated only in the rat: one has seen nothing like them in mice or men.

In the end, Prof. Selye ("Overview", p. 403) is driven to conclude that "the mast cell is a pluripotent cell, a kind of 'emergency kit' which contains a number of compounds that tissues may need, especially in regions exposed to local stress". This would certainly find more favour with me, as I have myself been advocating a local 'mast-cell cycle', intermittent in action and motivated by trauma, for the past dozen years (*Lancet*, i, 841; 1954). Perhaps the real 'emergency kit' is the book itself. No future explorer on the mast-cell trail can afford to travel without it. Author and publisher alike are to be congratulated on a splendid achievement. JAMES F. RILEY

BONE

Proceedings of the Second European Symposium on Calcified Tissues

Held at the Domaine Provincial de Wegimont, March 31st–April 4th, 1964. Edited by L. J. Richelle and M. J. Dallemagne. Pp. xv + 471. (Liège: Université de Liège, 1965.) n.p.

CALCIFIED Tissues contains forty-six contributions on cell differentiation, fluorine, bone remodelling, collagen and kinetics of bone metabolism. It opens with a paper by Prof. F. C. McLean, the recognized doyen of osteology, summarizing some of the progress made in recent years towards the understanding of the mechanism of internal bone remodelling. The picture, while a hopeful one, is far from being rosy, for, as the speaker recognizes, the resorption cavities originally described by Tomes and De Morgan more than a century ago are still not well understood to-day.

Parathyroid hormone seems now to play little or no part in the remodelling of compact bone, contrary to the belief upheld until recently by most people. The concept of 'calcifiability' of the organic matrix is gaining support together with the belief that local acidity, probably caused by the metabolic activity of the osteocytes under the partial control of vitamin D and the parathyroid glands, is responsible for the solubilization of bone mineral.

It is beyond my powers to comment on most of the contributions but attention will be paid to a few of them; beginning with the work on cell differentiation by the use of tritiated thymidine and tritiated glycine by Maureen Owen, who found evidence in the periosteum of the femur of young rabbits of the negligible role that the fibroblasts take in increasing cell population in the active bone-forming layer of the periosteum. The pre-osteoblasts, on the other hand, increase at a rate of about 33 per cent per day while the osteoblasts take an average of 3 days to lay down the matrix and become osteocytes. This work contributes substantial evidence that the specialized cells of bone are all different functional states of the same cell and that they can revert easily from one state to another. No conclusion is reached as to the origin of the progenitor cell but the suspicion is advanced that it may be a fibroblast, while no mention is made of the possibility that the source is the vascular endothelium which in perfused specimens is seen to occupy exactly the mid-position between the fibroblast layer and the pre-osteoblast.

Vaes contributes with a good paper in support of the view that the production of acid hydrolase of bone is segregated within special particles surrounded by an impermeable membrane analogous to the lyosomes found in liver.

Danis and Donizel in a paper on heterotopic ossification advance the view that the pre-osteoblast originates from migrating white blood cells. In this work they do not use vascular perfusion to determine the relative position of the vessel wall and the line of ossification.

The field of osteoporosis is well covered by several papers; in one of them Pratt and McCance add further data on the atrophic changes induced in the pig by under-nourishment, contributing with the finding that bone in this condition was always hypercalcified, reaffirming the previous observation that bone from an undernourished animal was as heavy as a bone of the same length from a well-nourished animal. Chalmers brings data on the different survival rate of the growth and articular cartilages in grafted limb rudiments, and Rutishauser and Tschantz investigate the early effects of pressure on bone. These are the only contributors who refer to the vasculature of bone and conclude that remodelling in the cortex under compression depends on the proximity to or separation from the vessels.

A detailed and lengthy work on collagen by Tristram and the discussion of his paper by Horman make a section by themselves, complemented by two or three other works on the subject.

The relation of bone matrix lipids to calcification is examined by Irving, while Ascenzi and Bonucci investigate the changes in the tensile strength of isolated osteons with advancing age and conclude that calcified and decalcified old osteons have tensile strengths of similar magnitude. This brings further evidence that the collagen fibres of the matrix mainly determine the mechanical properties of bone tissue.

Foster and his collaborators present the result of their investigations on the origin of calcitonin or hypocalcaemic factor, favouring the view that the thyroid is the source of this hormone and not the parathyroids. Haas and collaborators add evidence that calcitonin, so far demonstrated to be present in the dog, is also likely to operate in man.

It is sad that an excellent paper on autoradiography in the study of phosphates in bone is the posthumous work of Prof. J. Vincent.

Summarizing, this volume contains material by many of the experts on calcified tissues and thus makes available works appearing in journals scattered around the world. To me, a limitation is still evident which may explain the lack of progress in some respects pointed out by McLean in his introductory remarks; this refers to the lack of interest in studying the part that the circulatory system, both in its container—the vessels—as well as in its contents—the blood—plays in the regulation of the unending process of bone deposition and bone removal. Apart from a couple of paragraphs by Rutishauser and his group, no reference is made to this important factor in osteogenesis.

J. Trueta

A SUPERFICIAL VIEW OF MENTAL HEALTH

Mental Health in a Changing World

Edited by Kenneth Soddy and Robert H. Ahrenfeldt, with the assistance of Mary C. Kidson. (Vol. 1 of a Report of an International and Interprofessional Study Group convened by the World Federation for Mental Health.) Pp. xxiv+192. (London: Tavistock Publications, Ltd., 1965.) 35s. net.

THIS is a disappointing book. It is a report of the work of sixteen psychiatrists of various nationalities, two psychologists, two child psychologists, a biologist, an anthropologist, an educationalist, a scientific journalist, and a priest.

They formed a study group, first convened in 1961. Unfortunately, the journalist died and another member had to leave for emergency surgery. The rest were in continuous consultation from June 12 until June 24, 1961; but it is difficult to discover from the book how many times, if at all, they had further discussions.

The material for discussion was arranged into eight sections, which were further sub-divided. They consisted of clinical, research, prophylaxis, professional training, public education in mental health, mental health implications in other fields of science and professional practice, mental health implications in social and community life, and mental health and cultural attitudes.

One might have expected with such a distinguished study group, covering such a wealth of material, that something akin to the symposia of the Ciba Foundation Colloquia might have resulted. This has not occurred.

Thirty pages, out of 120, are devoted to the introduction, the background of the study group, and its work. The other 90 describe its conclusions. The rest of the book is composed of the bibliography. The conclusions are platitudinous and banal: the style is dull, pompous and repetitive. No doubt this is partly due to the death of the scientific journalist, but it does not add interest to the book.

Nothing fresh seems to have emerged, but some of the statements are dubious and do not bear examination. For example, it is stated that: "The very fact that some form of compulsion is necessary to get boys to fight in any national war is suggestive evidence against the assumption that war represents an outpouring of a national aggression which must inevitably find expression in that particular manner". Such a statement is not true; some young men do not need compulsion, some even welcome a chance to fight. Only in those who need compulsion is there lack of aggression. Most of us have seen films of young Indians shouting to have a chance to fight Pakistan in the recent conflict.

Again, surely every psychiatrist appreciates that people are often suspicious of him because they feel that psychiatry can be used harmfully as well as beneficially. To retail anecdotes of a military psychiatrist being greeted by a general at the start of official conversations with "Don't try to psychoanalyse me" seems futile.

These are but two examples of the sort of material described. The complaint which can be made against the book is that it is an attempt to cover too wide a field, with resulting superficiality. Indeed, if, as seems to have been the case, there was only one period of twelve days to discuss everything there was obviously not enough time to do so adequately.

The bibliography is a valuable one, so far as it goes. It is composed of books published on the subjects discussed, between 1948 and 1962. There are 675 references with the addition of some 66 supplementary titles. It does not go beyond the summer of 1962 because, as the authors say: "We lacked facilities to ensure that the list of recent additions is complete". No explanation for this is given.

The index is adequate and the book is well printed and nicely bound in black cloth with gold lettering.

Two further volumes are promised from the International Study Group, but it is to be hoped that they are more profound, and more useful than the present one.

Clifford Allen

CHILD PSYCHIATRY

Modern Perspectives in Child Psychiatry

Edited by J. G. Howells. Pp. xvi+595. (Edinburgh and London: Oliver and Boyd, 1965.) 105*s*.

THIS omnibus volume is a 'double decker'. The lower deck is designed to provide the scientific basis of child psychiatry and the upper the clinical superstructure. Unfortunately, its designer has omitted to provide a connecting stairway. By and large, there is very little contact between those who write about the development of normal children and the experts in child psychiatry. Nor, it would seem, is a great deal being done in child psychology at present that looks like being relevant, in any direct way at least, to psychiatric issues.

The lower deck is occupied almost exclusively by academic psychologists, who write from a variety of points of view and with varying degrees of understanding of science and children. Indeed the most useful are probably those in which neither science nor children are particularly obtrusive. Among the topics dealt with are research methodology, genetical issues, the development of perception, thinking, remembering and imagining, and the application of learning theory to child psychiatry. There are also contributions written from the standpoint of ethology and (inevitably) that of Prof. Piaget. The child psychiatrist in search of a 'scientific basis' for his work must pay his money and take his choice—or, as is more probable, do neither.

The psychiatrists upstairs provide a more coherent picture, in so far as their work reflects the investigation of relatively well-circumscribed groups of disabilities, for example, speech disorders, mental subnormality, childhood psychoses and epilepsy. There are also chapters with a more distinctively social slant, such as those on delinquency and on the psychiatric aspects of adoption. For the most part, these contributions are well organized, up to date and surprisingly free from jargon. Only in one or two cases do preoccupations of a somewhat fanciful character obtrude.

Modern Perspectives in Child Psychiatry is neither sufficiently authoritative to be accepted as a handbook nor sufficiently original to be taken as a contribution to research. It does, however, bring together recent work relevant to a considerable number of important topics in its field, and the editor, Dr. J. G. Howells, merits warm commendation on the judgment he has displayed in his choice of contributors. Nearly all are good and there is surprisingly little overlap. His own review of the child psychiatric services in Britain is also extremely capable.

While omnibuses have their uses, they are undeniably cumbrous, and in some circumstances pretentious. The way to establish a more adequate scientific basis for any part of psychiatry is simply to undertake more and better research, which may or may not involve the systematic investigation of normal behaviour. What is wanted, it might be suggested, is an amphibious vehicle, equally at home in the disparate media of psychology and psychiatry, and able to carry out pilot raids on any part of the psychiatric coast line that might seem vulnerable to scientific attack.

O. L. Zangwill

BELIEF SYSTEM OF A CARGO CULT

Road Belong Cargo

A Study of the Cargo Movement in the Southern Madang District, New Guinea. By Peter Lawrence. Pp. xvi+291 +6 plates. (Manchester: The University Press, 1964.) 35*s*. net.

SINCE the late nineteenth century, many native-led movements, of varying intensity and duration, with the goal of quick acquisition of European goods, have appeared in Melanesia. Now Peter Lawrence's book, *Road Belong Cargo*, can join a small group of anthropological studies which describe and reconstruct particular cargo cults.

Lawrence's study is historically meticulous: he traces the impact of Europeans in the Madang District of New Guinea from Miklouho-Maclay in 1871 to the time of his own field work between 1949 and 1958. His account includes the economic changes, influence of missions, and reactions to administration. He pays particular attention to the relations between the races at different times, and he presents a full investigation of the life of Yali, the principal post-War leader in the area. Perhaps his most important contribution to studies of cargo cults is his analysis of the traditional belief system and historical account of the interaction of traditional belief and myth with mission teaching in the actual doctrines of the cults.

The five distinct cargo beliefs and other movements in the Madang area are described. They vary: pagan in the early days, Christian, syncretic, and later a pagan revival. In the course of these variations there were also shifts to anti-European hostility, and in the explanation of why the natives do not have the cargo they so greatly want. The bitter experiences with Europeans, and continued low economic status, brought, in later cults, militant nationalism. After the phase in which the natives realized that the Europeans are not deities, and believed that they forfeited rights to cargo because of their stupidity, there was in the 1930's a conversion to a kind of materialistic and anthropocentric Christianity. But as race relations declined, the following cult believed that the missionaries were holding back information; native deities were identified with God and Christ.

In the careful examination of the career of Yali as policeman, army recruit, leader of a rehabilitation scheme, and cult leader, we can see a combination of reality and fantasy which probably exists in many parts of New Guinea; it is clearly evident in some other accounts of native movements and their leaders—Tommy Kabu and Paliau. These movements are for local improvement: villages are rebuilt, clean living and hard work are urged for the common good, and some revision of custom is proposed. But periodically, under the influence of cult prophets, this road to cargo is abandoned in favour of ritual means. Lawrence gives us precise turning points: Yali's humiliation and disappointment in Port Moresby in 1947, and his acceptance of a new cult prophet a few months later.

Discussions of cargo cults often stress the abnormal thinking and hysterical behaviour of cultists, and present an explanation in terms of the suspension of the normal. From this investigation and a few others we begin to see that traditional beliefs in Melanesia are entirely compatible with the expectation of a divine gift of cargo.

Paula Brown

The Theoretical Significance of Experimental Relativity

By R. H. Dicke. (Documents on Modern Physics.) Pp. xii+153. (London and Glasgow: Blackie and Son, Ltd., 1964.) Cloth 32*s*. 6*d*. net; Paperback 17*s*. 6*d*. net.

THIS book is a reprint, without change, of the contribution by R. H. Dicke to the Les Houches Summer School in 1963, which originally appeared in the larger volume *Relativity, Groups and Topology*, published by Gordon and Breach (1964). Possibly because of a difference in paper, the overall appearance of the book is slightly less clear than in the original form. The author takes the position that the experimentalists should not be working on the complicated applications of general relativity but rather on its foundations. He begins by discussing null experiments like that of Eotvos, and then considers in some detail the three so-called 'crucial' tests. There are fairly complete references to experimental results, and the greater part of the book consists of appendixes—mostly on the author's characteristic theories of Mach's principle. The contents of these is best summarized by their titles: "Experimental Tests of Mach's Principle"; "Mach's Principle and Invariance under Transformation of Units"; "Long-range Scalar Interaction"; "Field Theories of Gravitation"; "Cosmology, Mach's Principle and Relativity"; "Significance of Spatial Isotropy"; "Mach's Principle and a Relativistic Theory of Gravitation"; "Lee–Yang Vector Field and Isotropy of the Universe"; "The Earth and Cosmology"; "Implications for Cosmology of Stellar and Galactic Evolution Rates"; "Dating the Galaxy by Uranium Decay"; "Dirac's Cosmology and the Dating of Meteorites".

The book fulfils a useful purpose in collecting together published work on experimental checks of the theory, although from a rather idiosyncratic point of view.

C. W. KILMISTER

Quantum Electrodynamics

By A. I. Akhiezer and V. B. Berestetskii. Translated from the Second Russian edition by G. M. Volkoff. (Interscience Monographs and Texts in Physics and Astronomy, Vol. 11.) Pp. xix+868. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1965.) 170*s*.

QUANTUM Electrodynamics gives a detailed and systematic presentation of quantum electromagnetic theory. Like all good books on the subject, it does not conceal the defects of the theory, and emphasizes that a complete removal of the unsatisfactory features of quantum theory will probably not be achieved without new and basic physical concepts. The authors have therefore given much care to expressing the existing theory in its most logical and consistent form; for example, in preparing this second edition of the book they have extensively revised the section on renormalization, so as to present the concept from a simple physical point of view, avoiding purely prescription-like methods of eliminating divergences.

The book is divided into nine chapters. The first chapter, which starts from Maxwell's equations and is devoted to deriving the quantum mechanics of the photon, is followed by a chapter on the relativistic quantum mechanics of the electron. In the next two chapters the Lagrangian, the method of second quantization, and the scattering matrix are introduced and explained in detail, leading to a chapter on the interaction of photons and electrons, and the retarded interaction between two charges. In Chapters 7 and 8 the investigation of the scattering matrix is extended to higher orders (radiation corrections). Finally, there is a chapter on particles of spin zero.

The great range of the book, and the mathematical detail of the applications, will make it a valuable reference book for workers in the subject; but it will appeal equally to non-specialist readers, since it assumes only a very elementary knowledge of quantum mechanics. Even when the mathematical development becomes very elaborate, the lucid accompanying text would enable the reader to obtain a clear idea of the procedure without following the mathematics in detail.

P. M. DAVIDSON

Dictionary of π-Electron Calculations

By Prof. C. A. Coulson and A. Streitwieser, jun. Pp. xxx+358. (London and New York: Pergamon Press, 1965.) 100*s*. net.

DICTIONARY of π-Electron Calculations is a compilation of the results of simple molecular orbital calculations on planar conjugated hydrocarbons such as polyenes, polyacenes, various conjugated radicals and hydrocarbons and some heteromolecules. It will be very useful to people who are interested in the electronic structures of conjugated systems; I have already used it twice in connexion with a series of lectures on electronic theory.

The essential thing about a compilation of this sort is that it should be accurate. The risk of error has been minimized by photographing directly the printed output of the Mercury Computer at Oxford. This is about as fool-proof a method of ensuring accuracy as one could reasonably demand.

The book also contains an introduction which outlines the essential features of the Hückel method. The introduction is an excellent little monograph which could be recommended to people who want to find out the bare bones of the theory. There is also a section entitled "How to Use the Tables", which will teach the reader something about elementary group theory. Altogether, a most business-like and attractively produced volume and one which should be on the shelves of every chemistry library.

H. C. LONGUET-HIGGINS

Technique of Inorganic Chemistry

Vol. 4. Edited by Prof. Hans B. Jonassen and Arnold Weissberger. Pp. ix+401. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1965.) 115*s*.

TECHNIQUE of Inorganic Chemistry is the fourth volume of a series which sets out to give an account of the techniques used in inorganic chemistry and contains, like its predecessors, a rather mixed selection of topics, of which the chapters on "Magnetochemistry" by B. N. Figgis and J. Lewis and "Optical Rotatory Dispersion and Circular Dichroism" by F. Woldbye are of the most immediate interest and value; both of these are very comprehensive and pleasingly written, and the book is well worth having for them alone.

Of the remaining chapters, those on "The Growth of Oxide Single Crystals from the Fluxed Melt" by E. A. D. White and "High Temperature Technique" by R. G. Bautista and J. L. Margrave are of less general application, but are likewise extremely interesting, well-written and documented accounts, and may well suggest potential applications of the techniques to the reader who has hitherto had no occasion to use them; the chapter on "Ion-Exchange" by R. Kunin is, unfortunately, far too brief an account and suffers, in comparison with the other chapters, because of its brevity and an extremely short bibliography, although it does give a fair picture of the uses and techniques involved.

This volume is as well produced as the earlier volumes, and there are very few errors of any kind; those observed were innocuous, such as the extra metal *d* electron in Cs_2CoCl_4 (Fig. 8, page 169), and actinides are not all transuranics and vice versa, as is implied on page 144. The value of the book, as of the rest of the series, lies in the good coverage of most of the topics and in the bibliographies; it is these which make it well worth having.

K. W. BAGNALL

IMPORTANCE OF TECHNOLOGY

By Prof. JAMES K. FEIBLEMAN
Department of Philosophy, Tulane University, New Orleans

PURE science—basic research—has been highly praised; but this is chiefly due to the products of applied science, in which the average citizen is able to see at first hand the brilliant results of science itself. The poor reputation of technology stands in sharp contrast to these successes. Although technology is very much older than the sciences, it is stronger than ever to-day. Yet it has never enjoyed great prestige. Such neglect is undeserved, for in technology the highest of human values are involved.

The term 'technology' comes from the Greek *téchnē*, a word for art or skill, a regular method of making something. But the meaning has shifted. Technology once meant very much what the Greeks meant by *èmpeiría*: a rule of thumb applied without any theoretical understanding of what is involved, to get something done which needs doing. To have a technology at one's command was *emperírōs tinòs échein*, to know a thing by experience. It is the skill of the practical man long accustomed to the doing. In the modern meaning of technology, however, a material tool is usually part of a 'short cut' method of accomplishment. Science is theoretical and technology practical. Science satisfies the need to know and technology the need to do. But since the seventeenth century we have learned that by doing it is also possible to satisfy knowing. We learn by doing but only if we have an adequate technology.

By technology now is meant the knowledge and use of the techniques and devices by which man exploits his environment to meet his needs. A given stage of technology is measured by its efficiency. The essential point seems to consist in getting a piece of matter or energy to move against another piece. An artefact—that is to say, a material object altered through human agency—is to be produced out of raw materials by tools in accordance with some process. This may mean one thing operating on or affecting another thing in some way or other. The operation is technological so long as it is physical and employs a physical instrument or technique.

Whenever in a field of endeavour the material objects designed or the practices used become routinized or modified as a result of experience, then we are in the area of technology. Every particular endeavour has its own technology, whether farming or inscribing cameos. Having a technology is a minimum requirement for any discipline. Technology is always at the physical level and always uses physical means, and this remains true whatever the end. Technology thus includes the large theoretical areas concerned with instrumentation. Getting things done with the kind of advanced technology rapidly becoming available does not mean doing them; it means designing instruments to do them. In this way applied science and technology are rapidly coalescing under the general heading of technology, with pure and applied science furnishing the theory, and technology the devices.

We still tend to think of technology only as the effort to solve a practical problem by trial and error with tools. The technologist is known to be one who tries to discover a new method of meeting an urgent need by improvising wherever the work has taken him and by using whatever materials are ready to hand. This is one of the meanings subsumed under the definition we have adopted. But this is a highly significant one. Indeed we seldom comprehend the sweeping implications of such a conception. For in this sense, all civilization has its origins in technology. The first ape-like man who stood erect in order to have his hands free to throw a stone at an animal too swift to catch was also the first technologist, for his action fits the definition already given here. This happened according to the most recent findings some million and a quarter years ago.

It is interesting that civilization can be dated from the beginnings of bipedalism, and that technology was responsible for bipedalism and not the reverse[1]. Men stood erect in order to throw stones, they did not throw stones because they were standing erect. Thus it is technology which is responsible for there being men at all. In technology we are turning the environment in a certain way against itself, getting it to take shapes by using parts of Nature against other parts in order to reach goals we could not otherwise reach. We have found that through the use of tools accomplishments can be on a grander scale. There are no records of human beings without tools. Even the most primitive people alive to-day, the Australian aborigines, the Bushmen of South-west Africa, and the Guaharibos of the Brazilian jungles, have tools of sorts: digging sticks, throwing spears and cooking pots.

Of course, man-made tools are not the only ones. There are bird nests, beaver dams, beehives and anthills, and many more. However, human toolmaking is advanced in several important respects over the others. There is a continuity to the human effort made possible by social co-operation. Furthermore, human tool-making is extended into the production of quite another sort of tool: the sign. Signalling systems of a complex character which added to the range of the human capacity rely on technologies. Writing and printing, the manufacture of paper and books, are technologies which make possible the storing of information, and thus provide for a continuity of effort. Since there were so far as we know no theories of communication antedating efforts at communication, it may be supposed that the earliest means of communication were products of technology.

Tools are material objects which have been altered through human agency. But the tools that man makes are responsible for marked changes in his behaviour. Tools in fact force skills. With each new technological device, a skill must be developed in order to use it. Technicians who excel in the operation of instruments have existed at all times. Some can throw a spear farther, others can write better, still others have a native capacity for designing and executing better utensils. More often than not the use of tools requires prolonged effort. Not everyone can bring a piano to its greatest proficiency, and evidently the same statement applies to the operation of spacecraft.

Life of the human variety is mainly due to the device of an interchange between animal and tool. Man makes tools, but then he is affected by them, and this can be observed in many of his adjustments and ailments, from

habituation to occupational diseases. What man makes in a certain sense also makes him, and as he continues to improve his tools he also continues to be altered by them. It is a rare thing now for anyone to encounter in his ordinary experience much of the environment that his fellows have not had a hand in re-making. The clothes he wears, the shelter under which he lives, the food he eats, the ground on which he walks, and almost the very air he breathes, is not what it would have been without the performance of some human operation. We have produced our own environment and we are continually being affected by it. Primitive man had a few very simple tools. Civilized man in a modern industrial society is surrounded by highly complex machines. The degrees of civilization between these extremes is determined to a large extent by the current stage of development in technology.

From the point of view of human behaviour, it is necessary to remember that although technology is ordinarily considered a means and not an end, the situation is not actually that simple. For means often influence the ends they serve, while ends do not altogether determine the means which shall be employed. A technical device or skill is a preparatory response undertaken in view of operant behaviour. But if technology is always the means for getting things done it still has to be decided what has to be done, and this is a question of preferences. The first use of tools by primitive man was to reduce his hunger. The human needs do not change, but there are changes in the decision of which needs are to be emphasized. And in the making of such decisions the availability of technological tools is extremely influential. To-day we are devoted to transportation and communication on which we are committed to the spending of a disproportionate amount of our income. But there have been cultures in which the individuals were far less concerned with such matters. Certainly the problems which occupied everyone in Tibet were quite different. The emphasis of the culture will determine what the problems are to be, and the technologists will then address themselves to solving them. The Chinese had steam engines millennia ago, but used them only to open temple doors. The Hellenistic Greeks understood and to some extent used mechanical devices, but they were not very interested in this approach. With them as with the ancient Chinese the technology of ceramics was pursued with far greater avidity.

And what is science after all if not a more deliberate kind of technology? It was by means of tools that man enabled himself to found institutions and advance to a higher stage of culture. We can see this if we examine the procedures a little more closely. Once man had gained a little headway in providing himself with the articles necessary for immediate survival, once he had stored a little food and clothing and taken measures to protect himself in advance against the encroachment of enemies, he found himself in possession of that rare commodity, leisure time. By utilizing it properly, which is to say, by thinking about the nature of things without regard to any particular need but only for the acquisition of abstract knowledge (which might conceivably have included the problem of the satisfaction of the needs in general), he could set about devising new and more efficient methods for achieving particular need-reductions in the future.

One of his needs was, of course, to satisfy his innate and powerful curiosity, and for this purpose there were things he could do as well as things he could merely think about. Scientific method so far as it is the method of pure science is directed toward theoretical ends. But then almost by chance he found that such theoretical scientific discoveries could have immense practical consequences. Applied science, so beneficial to man in a practical way, was found to be the application to human problems and needs of knowledge obtained in quite another way. By endeavouring to reduce his need to know, man has come on principles the application of which in practice was quite capable of helping to reduce his other needs: his hunger, for example, his need of accomplishment, his need for shelter and for medical attention. If these principles could only be implemented, the gain would be enormous.

Thus the line between technology and applied science became thin. The only difference is that technology is closer to the practical problem. What I am referring to when discussing science, applied science and technology are three grades of increasingly particular concrete approaches to the concrete situation. Through pure science the principles are discovered, through applied science the method of application is found, and through technology the actual practice is worked out. Usually three sets of men possessing three different sorts of temperament and having three different but related kinds of interest are involved. The first group consists in men of a theoretical turn—mathematicians and mathematically minded experimental scientists. Men of the second group uniquely combine theory with practice, but not with an equivalent interest: they must be familiar with the theory but only because they wish to put it into practice. The third group contains the men on the scene, practical operators who must solve immediate problems with a minimum of equipment in order to get things done.

Every use of an abstract scientific principle must always be an application to some particular concrete situation. The actual world is a rich one. It always contains more than is indicated by our limited schemes. Thus unexpected developments are bound to occur in the course of any human endeavour. These often tend to upset or defeat the plans of the applied scientist. New calculations must be made or new adjustments devised: and so it becomes the task of the technologist to meet such challenges to successful practice.

The development of technology has brought with it a whole host of attendant theoretical problems. The theory of general propositions required for scientific laws has proved difficult enough to formulate. From the classic Greek period to our own day, discussions on this topic have been conducted without reaching any satisfactory solution. This is not due to the peculiar character of the discussion but to the extreme complexity of the issues. But if a suitable theory of general propositions has proved difficult to construct, this is as nothing compared with the problems presented by the theory of the concrete individual. A material object or event is always involved in the labours of the technologist. Its analysis is a prerequisite of the understanding of his work. Such an analysis has scarcely been begun. Its successful outcome would be of great interest to the theoretical explanation of technology.

All abstract formulations are of necessity ideally and universally stated. The theoretical scientist is concerned with them. It is he who discovers a hypothesis but the experimental scientist who verifies or falsifies it in the laboratory, usually by testing the deductions from it. The speculative area of concern to the applied scientist is some particular sub-class under the indefinitely large class of the ideal formulation. It is the applied scientist who finds the special class of occasion on which a law can be effectively applied in practice. But the area of the technologist is narrower; it is some individual and particular occasion. The analysis of material is the work of the pure scientist. The way in which such materials could be combined or used in industry is the work of the applied scientist. But the way in which materials could be brought to bear to solve a particular task is usually the work of the technologist. He is the one who learns when he actually applies the law to a particular occasion that its application can be improved. He is the man on the site who cannot avoid the fact that an insufficient number

of variables were taken into account in the original formulation when this particular job was being planned.

In order to see how the technologist works, let us, for example, consider a problem in structural engineering. Suppose a river bridge is to be built. So far as this task is concerned, the work of the theoretical scientist was done long ago when he discovered the engineering principles which will of necessity be involved. His field is mechanics, the mechanics of shears and moments, of stresses and strains. The applied scientist is he who will make the calculations from mechanics which are necessary to solve the particular problems. Once he knows the maximum weight the bridge will have to bear, the width and speed of the river at the site, the character of the soil on the banks, and other details of this sort, he can design the structure and specify the materials.

But there are other problems more particular still which cannot be worked out in advance. For no matter how thorough and precise the calculations, difficulties which had not been anticipated are bound to present themselves as the work progresses, and these require the presence of an engineer. For example, test borings at the site may have indicated granite—but not broken granite: and so now the engineer must decide what to do. Should he go down into the stone another ten feet to see what the conditions are, or should he support the structure on the broken stone by increasing the footings sufficiently to take care of it? Again, somehow in designing the bridge, signal lights on the abutments had been forgotten, and he will have to make last-minute arrangements to install the necessary conduits. Finally, the expected stone copings for the abutments were not delivered. Should he try to produce a mixture of fifty yards of exceptionally strong and durable concrete to replace the stone?

Science, then, is not the same as technology; but the relationship becomes increasingly clear. Science is technology looking to its own future. A good illustration is to be found in present-day developments of projects intended to further the exploration of outer space. In the design of propulsion systems, in the techniques of launch, separation, re-entry, and recovery of spacecraft, to say nothing of the design of the booster rockets themselves, technology furnishes the means to applied science. The search for reliable knowledge by means of the scientific method is only a variant and a late development of the search for practical knowledge, and science itself a further stage of technology.

If technology and applied science are intimately related, so are technology and pure science. Pure science and technology are so inextricably interwoven that one has often led to the other. In the case of the steam engine the technology came first and the science afterwards. Carnot developed the physical science of thermodynamics after the investigations of the implications of the steam engine. In the case of atomic energy, the science of quantum mechanics came first and the technology second. Planck's work and that of many other theorists and laboratory experimentalists came before the atomic bomb and the plant in Shippingport, Pennsylvania. But in both cases, whichever came first, there is a technology and there is a science.

Finally, there is a certain sense in which it can be said that the scientific method itself depends on technology. Observing by means of instruments, setting up a hypothesis to account for the observations (and others of a like class not at present observable), testing for verification or falsification by means of experiments with still other instruments, and then making calculations from the established results, which we call the scientific method of discovery, is only after all a kind of advanced technology. It is a deliberate method built to replace the trial-and-error method, but one providing for surprises and containing the trial-and-error elements. It is, one might say, a planned technology rather than the classical sort of technology conducted under the pressure of exigencies, a way of anticipating the requirements rather than of meeting them at the last hour. Technology was once the way to improvise a practice, then it became the way to get from science to practice, now it is the step which facilitates both pure and applied science by means of invention.

For science would not be science without laboratory instruments, and applied science could not be applied without technical devices. In the former case, consider the enormous importance of the cyclotron, which has furthered nuclear research; and in the latter case, consider the aeroplane. In the case of Leonardo da Vinci, who speculated on the possibilities of flying a heavier-than-air machine, not only was the theory inadequate but the requisite technology was also lacking. With the proper theory but without the proper technology he still would not have been able to fly.

According to the meanings which have become established through usage, when an instrument is used to get a theoretical task done, we call it scientific; and when an instrument is used to get a practical task done we call it technological, even though the procedures used may be very much the same. Scientific advance depends on the development of laboratory instruments, and technological improvements make possible the progress of experimental science. Scientific advance rolls down in waves of concentration, from observations aimed at discovering regularities and through them the formulations of abstract laws, to the invention of new techniques and devices necessary if the laws are to be applied. The centre of interest shifts from the problem of how to discover new principles to the problem of how to provide new equipment.

Within the scientific method itself, in the step-by-step process by which it is conducted in the laboratory, one finds a host of particular technologies. In chemistry, for example, in selecting one at a time the techniques for analysing materials in order to discover their constituents and structure, one has at one's command if one is a professionally trained biochemist a number of alternative approaches, such as freezing, crushing, drying, grinding, solubilizing, heating in strong acid, suspending in fluids of various densities, centrifuging, evaporating, and many others. There is usually a 'working hypothesis' somewhere in the background, a proposition accepted as though it had been verified in order not to hold up the proceedings, and its consequences put to use when no experimental test that could result in verification has yet been devised.

Pure science cannot be tested in advance for utility. Fortunately, this is the case, for there are too many discoveries which are the result of chance, which is to say, of accident or the trial-and-error method. Technology, however, is not entirely hit or miss. It contains that kind of procedure too, but relies also on the intuitions of the technologist, his 'feeling for the job', based on years of experience of living with the tools and operations. Rubber was a discovery made by chance and improved by science. Often the relations of pure science, applied science, and technology are turned around. The discovery of free radicals, for example, was made by chance in the course of a routine scientific procedure and later adapted by technology to many practical purposes.

Science is certainly the best method which has thus far been devised for obtaining a certain kind of result. On the other hand, not everything is readily amenable to scientific treatment. The reliability of the method is all the more remarkable when we remember that it is not expected to yield certainty. For even the most accurate method known for deriving reliable knowledge is still only a way of probing in the dark. We do not know very much about what we shall find, and afterwards we can never understand altogether what we have found. The infinite abundance, the extent and complexity, of nature remain, however much we examine it, and always manage to escape our full comprehension. Hence the necessity

of having a last-ditch method of attack. Science will never accomplish so much that the more elementary approach to an unaided technology as a separate and independent becomes dispensable.

Science has reinforced technology—not eliminated it. Behind the technologist there is the theoretical scientist and his applied brother. They are able to carry the solution of the problem an immense distance—in fact, all the way to the frontier where work must at last be done. But at the frontier there always arise additional problems, and for these the skills of the technologist are necessary. The theorist was the one who estimated the amount of energy that would be released if the atom were split, and the applied scientist suggested how to split the atom and even devised a method for doing it. But it was the technologist who had to make the decisions when to pull the rods in order to slow down the reaction to a controllable rate.

In what is to-day called 'big science', the science of the linear accelerator and the orbiting astronomical laboratory, for example, exploration is a form of scientific experimentation and technology is the frontier. The bigger the science the more the problems solved on the spot call out the knowledge and skill of the experimenter. At this point technology becomes not only indistinguishable from applied science but also from basic research.

We tend to think of technology as physical, and so relate it to the physical sciences, and in particular the science of mechanics. It is not so limited. Every science has its technology, and there are many areas where no science ever existed which have their technologies as well. Every variety of human activity of the disciplined and formal sort has its own technology, the material means for getting things done. We think of technology as the practical side of physics simply because in it the two material aspects coincide, a physical means for doing physical things. But there are physical means for doing biological things, psychological things, and even anthropological things.

The technological frontier in the biological sciences is to be found in the adaptation of physical and chemical tools and techniques to the biological subject-matter. The applied branches of the biological sciences lie, of course, chiefly in the practice of medicine, and medicine was until recently almost entirely given over to the experience and intuitions of the family physician. The techniques used in the practice of medicine had arisen largely as a result of treating patients. Thanks to physics and chemistry, however, the scene has changed considerably. No one will deny that the progress made in medical practice in the past century equals that made in all the previous millennia. The rapid improvement can be attributed in large part to technology. The X-ray, the spectrometer, the electron microscope, did not emerge from practice but were introduced from the outside; and neither did the antihistamines, the antibiotics, the tranquillizers and energizers, which have produced such enormous improvements in therapy: these were the work of the biochemists. Technology contributed its part by bridging the gap between scientific discoveries and manufactured products. The intuitive method, of course, has been reduced, but it still exists at the bedside. But technology has taken over in the laboratory where the applied biochemist has the problem of reducing his theoretical knowledge to utilizable form. His instruments have to be continually invented or improved, and new techniques discovered or devised.

The technological frontier in psychology lies in such activities as the designing of instruments such as the animal maze and the Skinner box, and the devising of techniques for conducting experiments, for example, the implanting of electrodes in the brains of animals in order to test reactions.

Psychology is such a relatively new science that the pioneering of experimentalists often enables the technologist to take the lead. Consider, for example, the role of technology in Pavlov's earliest conditioning experiments. The invention of the dog's stand and special harness were necessary components, and made it possible for Pavlov to verify the existence of the conditioned reflex. In applied psychology, there is the professional use of the psychoanalyst's couch, the administration of electroshock, the injection of sodium pentothal as part of the technique of narcosynthesis, and the specially equipped tubs employed in hydrotherapy.

The technological frontier in anthropology relies on such technological aids as the carbon-14 dating method and various solutions for cleaning and preserving archaeological findings. Many trial-and-error methods of on-the-site reconstructions are resorted to by practical archaeologists. We have come to recognize in the recovered artefacts of a dead culture part of the technology of that culture.

Technology is far-ranging and cannot be confined to the sciences. The arts have their technologies as well. The equipment of the painter, for example, offers many opportunities for the practice of technology. New paints of a more durable sort have to be discovered, new surfaces adapted to the painter's needs. In our own day many industrial products have been used for this purpose. Painting on prepared surfaces with plastic paints offers many advantages. In sculpture new material media are available such as aluminium and welding iron. In music new electronic instruments have been invented, instruments with a larger range of sounds and more easily modulated. The technologist was always very much in evidence in music, which requires many precisely made instruments, such as the violin or the piano.

In addition to the pure sciences and the fine arts, which have long been in the habit of considering technological assistance adjunctive, there are still a large number of areas where technology alone prevails. Cooking is neither an art nor a science, but only a technology. The same could be said for a great many other trades, such as tailoring, lumbering, or even teaching.

To-day we are witnessing the rapid speed of technology. But such a prevalence has its attendant ills, the danger, for example, of living for technology instead of by it. Usually what we do is conditioned by what we can do. Wars have often been fought because they had been prepared. The transmission of vast accumulations of data brings with it the temptation to transmit vast accumulations of data even when such an operation serves no reasonable purpose. If men climb mountains because the mountains exist, it is also true that data are processed because of the rapid improvement in the technology of data processing. The threat to technology consists in not knowing how to use it properly, and misuse can consist as much in excess as in defect. In the direction of excess there lies waiting the danger of recessive tendencies, of populations weary of expensive toys and discouraged because the outlay of vast expenditures of capital and of energy has produced so little in the way of solid satisfaction: a gain in knowledge, perhaps, but not in human happiness. How much education will be required before a sufficient number of people can be made to understand that dedication to inquiry is the highest of human purposes? In this way they might authorize the society to continue its support. If the significance of technology were to fail, the patience with its increasingly large demands might fail also. We would not want that to happen when we are so near to the successful servicing of all human needs. The role of technology as the mediator between science and the other cultural values has yet to be sufficiently recognized and acknowledged, and this involves a certain risk to the continued achievement of the values themselves.

THE 1964–65 BELGIAN TRANS-SAHARAN EXPEDITION

By Prof. J. LÉONARD
Institut Royal des Sciences Naturelles de Belgique, Belgium

DURING the winter of 1964–65, under the leadership of Mr. Petiniot, the Belgian Trans-Saharan Expedition, sponsored jointly by the Minister for National Defence and the Minister for Foreign Affairs, accomplished the first crossing of the Sahara from the Atlantic seaboard to the Red Sea (Agadir to Safâga).

It was composed of a team of twelve, mostly military personnel (navigators, radiotechnicians, mechanics, a doctor, a nurse and others), and 3 heavy Unimog Mercedes lorries.

The most difficult travelling was between Faya-Largeau (north-east Chad) and the Red Sea, through some 1,500 miles of desert regions, very difficult of access, rarely explored and virtually unknown from the botanical point of view[1]. This fact and the impossibility for a scientist of visiting these regions on his own, unaided by the many facilities afforded by modern science, prompted the Minister for National Education to appoint a botanist to benefit from the exceptional opportunities offered by the expedition.

Route

Fig. 1 shows the route followed by the expedition across the Sahara. After having stayed several weeks at the Chad Research Section of the Office de la Recherche Scientifique et Technique Outre-Mer, Fort Lamy (Chad), in the northern Cameroon and on Lake Chad, the botanist joined the expedition at Faya-Largeau (Chad) and crossed the desert with it as far as Suez.

Collections

The materials brought back are:

(1) 564 *herbarium specimens* (J. Léonard 3340–3903), collected in the Chad (387), in the Cameroon (67), in Libya (40), in the Sudan (9) and in Egypt (53), among which 8 were algae collected by Dr. Onclin in Algeria (4), in Morocco (2), in the Rio de Oro (1) and the Niger (1). Many delicate flowers and fleshy fruits were preserved in liquids. All these collections have been deposited in the State Botanical Garden in Brussels, but duplicates will be shared with the Royal Botanic Gardens, Kew, and the Museum in Paris. The collections comprised 2 fungi, 4 ferns, many algae and 522 phanerogams belonging to 71 families, the most important being Gramineae, Cyperaceae, Mimosaceae, Papilionaceae, Caesalpiniaceae, Capparidaceae and Euphorbiaceae. Special attention was paid to collecting algae and plankton. Throughout the whole route, plankton was collected in each water-hole; 36 such samples and various algae have thus been collected. They make up a unique collection which has been found by Mr. Compère of the Brussels Botanic Garden to be, on a cursory preliminary examination, extraordinarily rich and varied.

(2) 195 *pollen collections* authenticated by herbarium specimens. They will be kept as a reference collection for the identification of fossil pollens when an effort is made to reconstitute the former vegetation which covered the Sahara.

(3) *Seed samples* of 117 species, which, sown in the Botanic Garden in Brussels, have already produced 62 seedlings and some specimens already in flower.

(4) *Samples of sand* collected in various localities on the route. These sands, watered, have already produced seedlings after a few days in the hot-houses, thus disclosing that they contained disseminated viable seeds. The determination of the plants will roughly outline the ephemeral vegetation that springs up after every heavy shower.

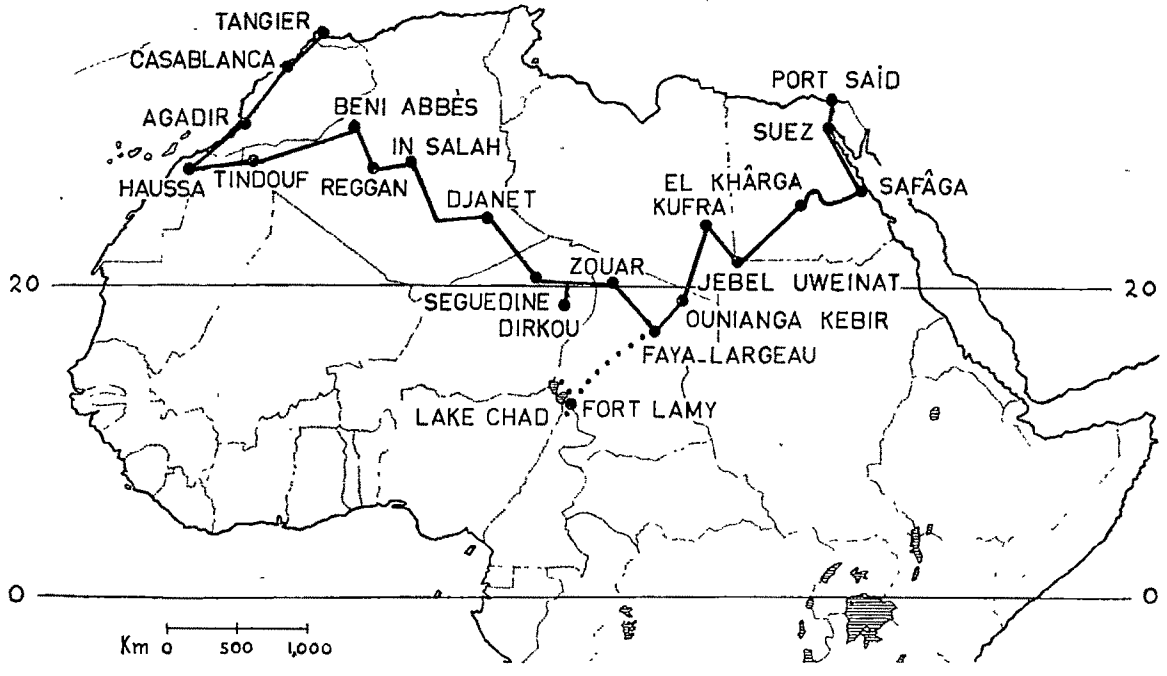

Fig. 1

(5) *Samples of various rocks.*

(6) *Fossils*, among which were silicified tree trunks, dating from the Cretaceous or the lower Eocene and half a lower mandible of a mammal living some 2–3 million years ago.

(7) *Many prehistoric tools* and more recent objects: carved stones dating back some 50,000 years, others 10,000 years, Neolithic polished axes, arrows, daggers, rings, necklaces, bracelets, etc. These collections have been deposited in the Ethnographic and Prehistoric Sections of the Museum for Central Africa in Tervuren, Belgium.

(8) *A colour film* illustrating the course of the expedition and several hundred colour slides illustrating landscape and vegetational types.

Botanical Researches carried out Prior to the Crossing of the Desert

Attention was specially concentrated on the aquatic vegetation in the region of Fort Lamy (Chad and Cameroon) as well as on the vegetation of the banks of the Rivers Chari and Logone: *Utricularia* and *Nymphaea* aquatic association, various aquatic grasslands (*Oryza*, *Vossia cuspidata*, *Echinochloa pyramidalis*, *E. stagnina*), riparian shrub vegetation periodically flooded (*Sesbania*, *Phyllanthus*, *Mimosa* and *Salix*).

Thanks to the kind invitation to join a foray organized by the Chad Research Section of the Office de la Recherche Scientifique et Technique Outre-Mer on Lake Chad, its little-known island and riparian vegetation were observed. The following plant communities were examined: aquatic vegetation (*Pistia* and *Lemna*; *Utricularia* and *Nymphaea*; *Potamogeton* and *Vallisneria*), semi-aquatic herbaceous vegetation (*Cyperus mundii*, *Vossia cuspidata*, *Echinochloa pyramidalis*, *Cyperus papyrus*, *Phragmites*, *Typha*) and also the wooded steppic vegetation of the sandy islands (*Acacia*, *Balanites* and *Leptadenia*).

The *Cyperus laevigatus* vegetation surrounding natron pools and ponds were examined in the course of a foray to the north of Lake Chad.

Crossing of the Saharan and Libyan Deserts to the Red Sea

The botanist joined the Trans-Saharan Expedition at Faya-Largeau (Chad), last important post at the edge of the desert. Ounianga Kebir (Chad) was reached after having covered 150 miles in a day and a half and collecting 26 plants. The expedition stayed there for ten days close to a lake situated in a paradisiacal landscape. The comparatively rich vegetation was intensively explored.

The oasis of Kufra, in southern Libya, was reached after having crossed the stark desolation of 460 miles, in two and a half days, of a stone and sand desert through which the track of the famous General Leclerc expedition of the Second World War was followed. On the last 400 miles, only five species of plants were seen and collected (*Capparis decidua*, *Cornulaca monacantha* and three different species of *Aristida*).

After studying the vegetation of the natron pools of Kufra, the expedition headed towards Jebel Uweinat, an important mountainous mass reaching 6,000 ft. and marking the boundary between Libya, Egypt and the Sudan. The 170 miles of country traversed were virtually devoid of vegetation. Only two species of plants were seen (*Cornulaca monacantha* and *Panicum turgidum*).

Many wadis radiate from the base of the Jebel. If they were dry at the passage of the expedition, they were nevertheless carpeted by a fairly dense and very interesting vegetation made up of about twenty-five species, nearly all in flower. Jebel Uweinat itself is a mountainous region barely known (certainly not with regard to its flora), the exploration of which should be of the greatest interest deserving of specialist investigation.

After having to endure a sand-storm, some 500 miles of most barren desert were covered in three days. What vegetation existed was strictly localized at the foot of the mountains lying on the route. Elsewhere, only rare tufts of *Aristida zittelii* were seen at long intervals. This region of very difficult access is most rarely visited although it reaches into the heart of Egypt close to the oasis of El Khârga. On reaching this place, the signature of the famous German botanist Schweinfurth was found engraved on the ruins of an old temple; he had visited this place a hundred years ago.

Having crossed the Nile, the expedition drove on once more into barren lands until the Red Sea was reached and later the Gulf of Suez and Suez itself. Thanks to recent rains, abundant collections were possible in the wadis and the ephemeral vegetation was examined.

Researches carried out during the Crossing of the Desert

Although time was very limited and insufficient to carry out any elaborate investigations, the following plant communities were nevertheless examined: aquatic vegetation of salt or natron waters with *Chara* and *Ruppia*; semi-aquatic herbaceous vegetation near freshwater springs with *Cyperus mundii* and *Paspalidium*; riparian herbaceous vegetation of the salt and natron lakes with *Cyperus laevigatus* and *Juncus*; herbaceous vegetation of the more or less moist sands with *Sporobolus spicatus*, *Imperata cylindrica*, *Desmostachya bipinnata*, *Panicum* and *Aristida*; vegetation of the sub-desert steppe with *Acacia*; vegetation of the grass steppes with *Chrozophora*, *Fagonia*, *Aristida*, *Aerva* and *Cornulaca*, and also the various vegetations of the wadis with *Aristida*, *Tribulus*, *Cleome*, *Aerva* and *Astragalus* (Jebel Uweinat), with *Aerva*, *Artemisia*, *Zilla* and *Zygophyllum* (between the Nile and the Red Sea), with *Haloxylon* and *Zygophyllum* (Red Sea) and with *Haloxylon*, *Panicum* and *Retama* (between Suez and Cairo).

Observations were also made on the adaptation of grasses to the wind-blowing of sand and their influence on their fixation. The indigenous food plants were also investigated.

Lastly, lists of vernacular names in the Gorane dialect and in Arabic with corresponding Latin names were drawn up for all plants encountered between Faya-Largeau and Jebel Uweinat.

An Edible Alga

In the market of Fort Lamy (Chad) one can purchase a greenish edible substance called *Dihe* which is sold as a flat cake. According to the information obtained in the market, it appears to be an alga collected on the bottoms of seasonally dried-up ponds and shallow waters in the north of Lake Chad and consumed by the local population. As the harvest period did not coincide with the visit of the botanist the inquiry was not carried further.

However, on arriving in the region of Ounianga Kebir, right in the middle of the Sahara, more than 750 miles to the north-east of Fort Lamy, the botanist was struck by the abundance of a microscopic alga in some lakes where it forms a real mash, easy to collect with a plankton net. Although the local population appears to be unaware that it might have a food value, the botanist suspected that it might be the same alga as that sold in cakes in the Fort Lamy market; he prepared some cakes according to the recipe obtained at the latter.

Both cakes, those bought in the market and those prepared at Ounianga Kebir, were examined by Mr. Compère (State Botanical Garden, Brussels). They are almost exclusively composed of a Cyanophycea: *Spirulina platensis*. Further, according to chemical analysis carried

out at the Laboratoire Intercommunal de Chimie et de Bactériologie in Brussels, it appears that it is a food-plant very rich in proteins and therefore very useful for consumption by the protein-deficient desert nomads.

Investigations are proceeding in this respect (chemical analysis, cultivation, ecology, etc.).

The Expedition has proved that, in spite of the many difficulties set by the terrain and above all those of petrol and water supply, it is possible to cross the Sahara from west to east provided proper equipment, specialists and technicians are available.

From the scientific point of view, the results of the expedition can be qualified as fruitful, not only from the abundance and quality of the material brought back, but also by the investigations which will result from it, and, perhaps later, the development of these regions, some perhaps barren, but others the wealth of which still is to be revealed.

PATTERN FORMATION IN AGGREGATIONS OF ENTITIES OF VARIED SIZE AND SHAPES AS SEEN IN MOSAICS

By RICHARD E. M. MOORE

Anatomy Department, Guy's Hospital Medical School, London, S.E.1

ANCIENT floor-mosaics provide material for investigating the formation of geometric patterns from the packing of irregular cubes in one plane. In contrast, modern mosaic stones are normally either uniform in size and shape or cut to suit.

More than 1,000 Roman and Greek mosaics were examined, largely from England, Italy, North Africa and the North East and East Mediterranean, and dating from *c.* 400 B.C. to about A.D. 530. As recently as 1955 the procedure of the mosaicist was regarded as unknown[1]. Apart from contributions[2,3] to the solution of this problem, the investigation has lent support to the hypothesis[3] that the packing of particles which vary randomly in sizes and shapes, within extremes, favours alignments of these particles at calculable intervals. This derived from investigations of bubble rafts, sand crusts, scums, the cells of leaves, and other particulate systems. It was also approached from a mathematical point of view (to be published elsewhere) considering random packing of cubes, irregular shapes and of spheres. Much attention has been directed to sphere packing[4], but the theory of cube packing has apparently not been investigated by others[5].

Materials

In simplest form a mosaic pattern is an area of stones of colour different from the others. The area is often circular or rectangular (Fig. 1*A*). A frequent pattern is a 'tracery' of stones of different colour from those forming the 'background' (Fig. 1*B*). A 'tracery' pattern often consists of several rows of stones, thus forming a thicker band (Fig. 1*C*). 'Tracery' patterns may be complicated by the band being itself patterned (Fig. 1*D*), or by a decorative rim (Fig. 1*E*).

Investigations of several thousand stones from floor-mosaics showed them to vary considerably in size and shapes within extremes, in each mosaic, in a largely random fashion. Trial also shows that 'random' stones result from the methods (to be published elsewhere) probably used in antiquity for stone manufacture.

In floor-mosaics, stones that disrupt patterns (but which would have been suitable for use elsewhere) were frequently found, indicating that they had not been carefully picked by the mosaicists, but used 'as they came'. In contrast, stones of wall-mosaics were apparently often specially cut to fit. Some wall-mosaics are more akin to marquetry.

That stones in floor-mosaics were not specially spaced out so as to conform more closely with the attempted patterns is apparent from the stones being tightly packed. Removal of the cement shows that even stones widely separated at the surface of the mosaic are often in contact deeper down.

The difference between the ancient floor- and wall-mosaic crafts was sufficient for the workers to be known by different names (for example, *tesselarii* and *musivarii*, respectively[6]). Wall-mosaic workers were largely concerned with pictorial scenes, often using materials unsuitable for flooring. Mosaic floors were normally ground smooth, whereas the stones in wall-mosaics were frequently of reflective materials.

Some floor-mosaics have, at the centre, a small, finely constructed mosaic picture. Because these 'centre-pieces' are so different from the surrounding mosaic (and from floor-mosaics generally), but exhibit the peculiarities of wall-mosaics, it is likely that they were made by wall-mosaicists. This is further indicated by these centre-pieces being set in trays (still remaining in the floor) and thus at one time would have been portable mosaic panels. These are known as *emblemata*.

An examination showed that stones for floor-mosaics were normally formed by breaking, but some of the earliest Greek ones are natural pebbles. Measurement of about

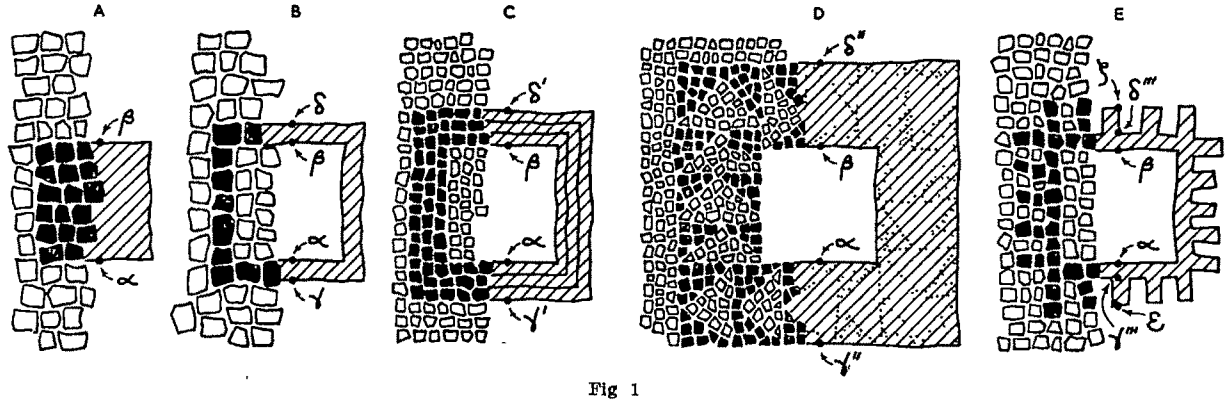

Fig 1

30,000 stones shows a typical modal size of their top faces (per mosaic) to be very nearly 1 cm × 1 cm. Some mosaics consist of stones about 0·2 cm, whereas others have a modal value greater than 4 cm. A typical size ranges between −48 per cent and + 34 per cent of the modal value, but is often greater (> ± 55 per cent). Ranges are normally smaller for small stones, and curiously for the larger stones also. The medium sizes exhibit the greatest ranges.

The stones generally lie in rows. Their dimensions measured tranversely to the row are normally more constant than their dimensions longitudinal to the row. From observation and experiment, the size of a stone appears to depend partly on the material used. It is often said that the average size of stones depends on date of construction, but the small number of measurements relied on, and the uncertainty of dates, do not allow a definite conclusion.

It is common to find two distinct sizes of stones in a floor. The bigger stones, of 3–4 times the side length of the others, exist solely as a peripheral region occupying the space between the perimeter of the true mosaic and the walls of the room. Mosaics are often set slightly askew with respect to the contemporary floor limits, and are sometimes considerably smaller than the area available. In England, these big stones are normally broken tiles.

Observation : Mosaic Growth

Stones which are unusual in size, shape or positioning with respect to their neighbours were found to give rise to distortion on one side only (Fig. 2). This implies that the stones in the distorted region were positioned progressively away from the 'abnormal' one. Inspection of many mosaics showed that these directions point away from the mosaic centre (away from one end in the rare repetitively patterned corridor mosaics).

The relative severity of errors and irregularities increases with the distance from the mosaic centre, and this also indicates growth from the centre. Detailed investigations of the relative positions of cause and effect disturbances indicates that the mosaicists proceeded fastest along the four axial directions of the mainly square mosaics. This is corroborated by irregularities being generally greatest in the diagonal regions.

Some parts of patterns are slightly distorted by following the shape of a near-by motif. Because the motif lies on the side of the pattern that is nearer to the mosaic centre, 'centrifugal' growth is again indicated. The same thing is suggested by the locations of stones that are misaligned in the manner of the stone marked *X* in Fig. 5, for these follow the adjacent row of stones that lies nearest to the mosaic centre.

Analysis of patterns that are not centred on the mosaic centre shows the evidence to be less simple, but also points to growth by accretion away from the mosaic centre that proceeded fastest axially.

The lack of alignment between the peripheries of mosaics and the perimeters of the floors, which contrasts with the frequent accuracy of position of the mosaic centre relative to the floor centre, also indicates centrifugal growth.

Hinks suggests[7] that lack of relationship between mosaics and rooms is due to the mosaics being "casual ornaments". Blake's explanation[8], that the mosaic periphery was reconstructed during replastering of walls, is seldom applicable, and does not explain mosaics lying skew. Trial shows that using stones 'as they come' and starting from the centre often causes the mosaic perimeter to turn out skew with respect to the floor. To allow for this, it is best to make the mosaic smaller than the floor. That there existed a lack of concern that decorations should fit the room structure is apparent from the irregularity of geometric patterns painted on walls. Because the discrepancy between mosaic and floor limits is often filled by large stones, Blake's reconstruction proposal in part gave rise to the idea that the size of the stones increases with date.

Trial shows that the positioning of a mosaic stone is easy or difficult according to the number of stones bounding it. The difficulty also depends on both the positions of such bounding stones, and the sizes and shapes that they happen to be. It can be shown mathematically (to be published elsewhere) that the sequence of positioning stones that involves minimal difficulty is one of accretion; it can also be shown that this sequence should start at the mosaic centre (start at the mid-point of one end of 'corridor' mosaics), and should be fastest in the axial directions because of the typical arrangements of the patterns. This would explain why mosaics were apparently constructed in this manner: the mosaicists had been using the simplest method, which they presumably learnt from experience. Volunteers, ignorant of the findings here described, proceeded—after a while—in a similar fashion.

Comparison of the gaps between stones where special spacing might be likely (to cause closer coincidence with the intended patterns, that is, immediately preceding a boundary), with gaps where special spacing was unlikely, further indicated that the stones were not specially spaced. A similar investigation of the sizes and shapes of the stones corroborated that they were normally neither specially selected nor specially shaped. Triangular stones are rare in floors, but mostly occur in positions where they are better than approximately square ones (Fig. 1*D*). However, they are very variable in size and shape, and were apparently made by cracking a 'square' stone into two; trial shows this to be easy.

An investigation of gaps, the ways in which errors and irregularities occur, and of vertical sections of a further 83 mosaics, indicates that floor-mosaics were constructed *in situ*. This agrees with Toynbee's conclusion[9], which is based on signed mosaics, travelling mosaicists, figure compositions of local materials, variations in different mosaics reproducing the same scene, and finally decorative surrounds of fine workmanship which form units with the picture they enshrine. This contrasts with Ippel's proposal[10], prefabrication by sticking stones face down on to sheets, but he was more concerned with figure scenes.

The imperfect alignment of mosaics and room margins, and the ways errors and irregularities are distributed, suggests that mosaic designs were not marked out beforehand. This is also indicated by the presence of mistakes of a type which, had they been made in a plan beforehand, would surely have been rectified.

Trial shows that the use of haphazardly variable stones, more or less 'as they come', makes it virtually impossible to match a design on the floor accurately.

The use by the mosaicist of stones 'as they came' appears to result from the technique of not shaping them to suit. If unsuitable stones are rejected great wastage results,

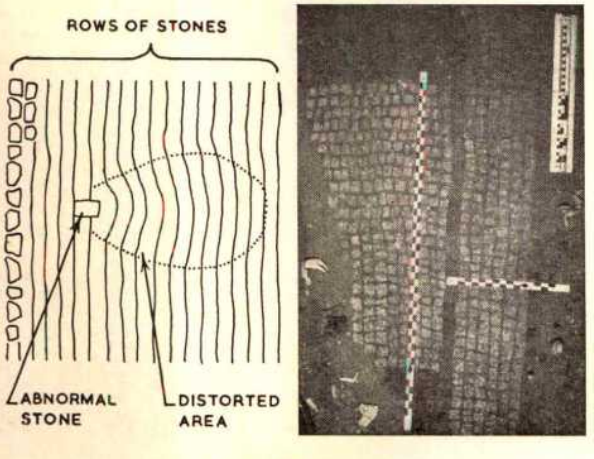

Fig. 2

which is unlikely, considering their probable source (to be published elsewhere). Trial shows that saving unsuitable stones for use later causes eventual acute difficulty.

It is a common belief that the mosaicists worked from 'pattern books' which showed the detailed positions for the stones. However, since 'pattern books' could not be matched by 'random' stones, it appears that, if they existed at all, they would simply be of a form useful to show to clients. Similar patterns exist on different mosaics, but consist of different stone arrangements. The existence of similar patterns is not itself evidence for 'pattern books', for the limited number of usable geometric patterns gives rise to a limited number of basically different results. This, and the fact that certain patterns were popular on other objects, would make it strange if many mosaics were not similar.

Observation : Pattern Sizes

In ancient floor-mosaics geometric patterns were produced from packing stones which vary in size and shape in a haphazard fashion within certain extremes; it would seem that these stones were apparently generally used without special selection, special shaping, or special spacing. Thus, if the hypothesis outlined at the beginning were correct, the mosaicists might have found by experience that the stones became more even at certain distances, and utilized this by basing their patterns on these particular sizes.

A pilot study showed that geometric patterns, taken from many different mosaics, nevertheless tend to fall into a few particular size groups. In some patterns only one dimension was needed for this purpose (for example, length $\alpha\beta$ in Fig. 1*A*), in others two or more (lengths $\alpha\beta$, $\gamma\delta$ and $\varepsilon\zeta$ in Fig. 1). It was found that each pattern in a 'size group' has one dimension of (virtually) equal length, despite great variations in pattern details (for example, length $\alpha\beta$ is constant throughout Fig. 1).

The existence of the 'size groups' may be explained by assuming that the mosaicists fixed the sizes of the patterns by using only a few alternative lengths, and that they used the same length for each pattern of the same 'size group'.

Because these equal lengths of different patterns are frequently composed of different numbers of stones, it appears that these distances were fixed by measurements and not by counting the stones. Equal lengths in the same pattern often consist of different numbers of stones (for example, Fig. 1*A*).

In a 'tracery' pattern of stones of slightly varying widths it might be expected that the rim of the pattern which was guided by measurements would be smoother than the other rim. In patterns which display one smoother rim, this is normally the one to which the measurement was made that was common to each pattern of the same 'size group'. Since these were usually the inner rims, it appears that the mosaicists normally proceeded by making measurements to these parts of their patterns. This agrees with centrifugal growth of the mosaics.

Some circular patterns tend to have a slightly square form (Fig. 3*A*). This effect could be correlated with the presence of an obvious stone located at the centre of the circular pattern ('obvious' because of its colour). Radial measurements of the circular pattern from the edges (see Fig. 3*A*) of this central stone were found to be more constant than those taken from any other central feature, real or imaginary. This suggests that the circular pattern was placed by measurements from the perimeter of the upper face of this stone, thus causing 'square' distortion. This is also indicated by the fact that this distance corresponds to the one that is common to each pattern of the same 'size group'.

'Square' distortion might be explained by mere packing of stones, apart from any measurements. However, examination of packing indicates otherwise. Moreover, a few cases were found in which one corner of the upper face of the central stone was incomplete, but was complete beneath the mosaic's surface. Thus the perimeter that could be used for measurements differs from the 'packing' perimeter of the stone. In such cases, the part of the circular pattern nearest the incomplete corner of the central stone is flattened, which indicates that distortions of circle patterns are a result of measurement rather than of packing.

This conclusion is supported by the observation that circular patterns around a real central point (for example, one formed by the meeting of four middle stones in a chequer pattern—Fig. 3*B*) are free from these distortions.

Comparison of circular patterns with a central point with those with a central stone (within the same 'size group') shows the former to be slightly smaller than the latter (Fig. 3), and by an amount equivalent to the size of the central stone. The explanation of this is that mosaicists probably used the same unit of length in both situations, measuring from the central point where it occurs, but from the perimeter of the central stone if one exists.

This suggests that the mosaicists preferred to measure from real features. Thus, where circular patterns lack both a central point and a central stone, and have instead a central motif devoid of suitable central feature, it is unlikely that the mosaicists used radial measurements. Diameters seem most likely, but the resulting 'circle' would tend to be an equi-diametric curve, as indicated in Fig. 4. This was, in fact, found to be the case.

Such 'equi-diametric' distortions again suggest that the pattern was not marked out before construction, for radii would then have been likely, obviating distortions of this nature. This consideration, together with the probable presence of the central stone at the time of making the measurements for circles exhibiting 'square' distortion, indicates that constructional measurements were made during the laying of the stones, and not beforehand as part of a preceding design.

Stones surrounding *emblemata* were found simply to follow the irregularities in the tray of the *emblema*, which indicates that the mosaic was constructed around it, as opposed to its being inserted into a hole left for its reception, as has been assumed by others.

Comparison of the eight radial measurements indicated in Fig. 3*A* on circles with a central stone was used to investigate ancient errors of measurement in these patterns. Similar observations were made on other patterns, and these in total show that the error was independent of the length of the measurement. This indicates that the mosaicists' measuring tools did not give increasing error over greater length, which excludes string, calipers (hinged), and 'spanning' by hands and

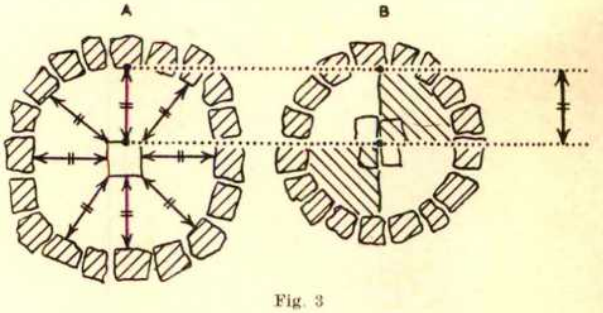

Fig. 3

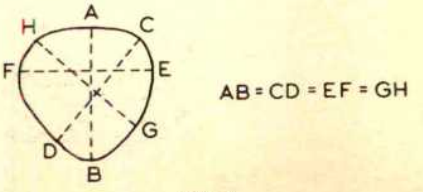

Fig. 4

fingers, but is strong evidence for rulers. The smallness of such ancient mensural errors also points to rulers, for those of the classical type that still exist (calibrated in still inadequately examined units) are mostly square in section with calibrations running around at least two faces, which reduces parallax error. That mosaicists used rulers is corroborated by the distortions evident in circular patterns already described here.

In concentric patterns where a circular pattern encompasses another, and no real central feature exists as a feature for measurements, 'equi-diametric' distortions will tend to occur in both patterns. If they were constructed independently by diameters, distortion of the outer pattern would not necessarily echo that of the inner pattern. Alternatively, if measurements for the outer were made from the inner, the outer pattern would follow the shape of the inner pattern. Since the latter is consistently the observed condition, it appears that the measurements for the outer pattern were made from the inner. This seems only natural when the inner pattern covers a large area and the outer pattern is only narrowly separated from the inner. Trial also shows that it is best to keep each constructional measurement short in order to avoid referring so far back in the mosaic that newly laid stones have to be trampled on when checking the zero of the ruler.

Pictorial mosaics of rectangular shape often exhibit opposite sides of unequal length and out of parallel; yet their outer bordering patterns lie at a uniform distance from their inner bordering patterns. Again, this is presumably a result of making the outer pattern equidistant from the inner. Because the innermost pattern is this shape (such that it could not have resulted from use of equal constructional lengths), it is unlikely that its form was itself guided by measurements.

In the case of more than two concentric patterns, it is likely that the constructional measurements for each pattern were made from the nearest preceding pattern. Again, measurements would probably be kept as short as possible. As with other patterns, evidence of the 'smoothest rim' and 'common' dimension type indicates that each encompassing pattern was normally laid by monitoring its inner rim. To decide whence, in the preceding pattern, this measurement was most likely to have been made, one can look where the already described 'common' dimension occurs. It is then found that this normally applies to measurements from the inner rim of the preceding pattern when the latter is narrow (Fig. 5*A*), but to measurements from its outer rim when it is wide (Fig. 5*B*).

The width of wide patterns was apparently similarly controlled by measurement (length *ab* in Fig. 5*B*), being often identical to the 'common' dimension of patterns of one of the smaller 'size-groups' (for example, length $\alpha\beta$ in Fig. 1).

The probable location of the ancient constructional lengths has become clear in many other geometric patterns.

If we accept that mosaic growth proceeded fastest in the four axial directions, then the first parts of each pattern to be reached in construction would have been those lying in these axial directions: consequently it would have been to these parts that constructional measurements would primarily have been made.

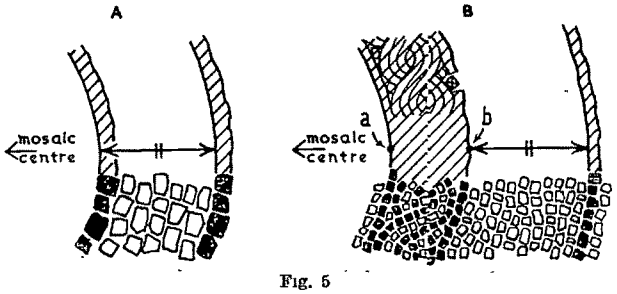

Fig. 5

Mosaic Units

To determine the probable values of the distances marked on the rulers of the mosaicists, a large number of distances was measured coinciding, as closely as possible, with the probable original constructional measurements on the mosaics. The frequency of their occurrence is shown in Fig. 6.

Measurement of more than 310,000 lengths produced the same distribution. The sample has since been increased with the same result. The vast majority of observed lengths are of closely similar values, forming ten major peaks (labelled *B*–$\bar{K}$ in Fig. 6), as well as many more minor ones. The total number of peaks formed is 106, but many of them are too small to appear in Fig. 6.

Each peak presumably represents one of the units of the mosaicists, the modal value of each approximating to the true value of each unit. The spread of each peak is a measure of the mosaicists' accuracy; to a small extent each is affected by my observational errors. If the relative heights of the peaks can be taken as a measure of the frequency of use of the various units, it is possible to equate the ten major peaks with the basic units of the ancient mosaicists.

Examination of Fig. 6 shows that several of the minor peaks occur at lengths which are multiples of the modal value of one or other of the major peaks. (These identifications are written sideways in Fig. 6.) These represent cases where patterns were occasionally made using multiples of a basic unit. Multiples of some major peaks give the same value as multiples of other major peaks. For example, the modal value of the minor peak at 36·0 cm is equally 3 *D* (modal value 6·0 cm) and 10 *C* (modal value 3·6 cm).

The modal values of the major peaks are: 2·4, 3·6, 6·0, 9·6, 15·6, 21·6, 25·1, 40·7, 65·8 and 106·5 cm respectively. These are the mid-interval values (class interval 0·1 cm). The standard deviation for each major peak is approximately 0·13 cm.

I shall call these ten basic lengths 'Mosaic Units'. 1·2 cm (peak *A* in Fig. 6) can also be counted as a basic unit, for it is probably important to the series in which Mosaic Units appear to lie. While in some mosaics this distance of 1·2 cm extends over several stones, it cannot exist in mosaics of stones larger than 1·2 × 1·2 cm.

Only minor peaks have been found at distances greater than Mosaic Unit *K* (106·5 cm), and this suggests that the rulers of the mosaicists were not normally longer than this. The most frequent lengths greater than 106·5 cm (peaks *l*–*o*) can be constructed with a ruler scaled in the Mosaic Units up to 106·5 cm.

Discussion

What little there is in ancient literature about the construction of mosaics largely stems from Vitruvius (first century B.C.). In the earliest extant version[11] of his work, which is believed[12] to have been written in the eighth century A.D., but which is equivocal and contains errors, a passage occurs, which in translation comments "over the *nucleus* accurately by *regula* and *libella* let the pavements be constructed whether *sectilia* or *tesseris*". The *nucleus* is the third foundation layer. *Regula* has been taken to mean a straight edge by some workers, but normally to mean a ruler. *Libella* is usually taken to mean a level. *Sectilia* probably refers to stones that were cut to shape, whereas *tesseris* almost certainly refers to the type of mosaic considered in this article. Perhaps it is to a Mosaic Unit ruler that Vitruvius refers.

Of the total sample of pattern dimensions observed, 89 per cent represent one or other of the Mosaic Units. Another 9 per cent are multiples of one or other of the Mosaic Units. A further 0·5 per cent are a fraction of a Mosaic Unit (usually ½ Mosaic Unit). Some of the remaining 1·5 per cent are identifiable as equivalent to ordinary units of measure current at the location

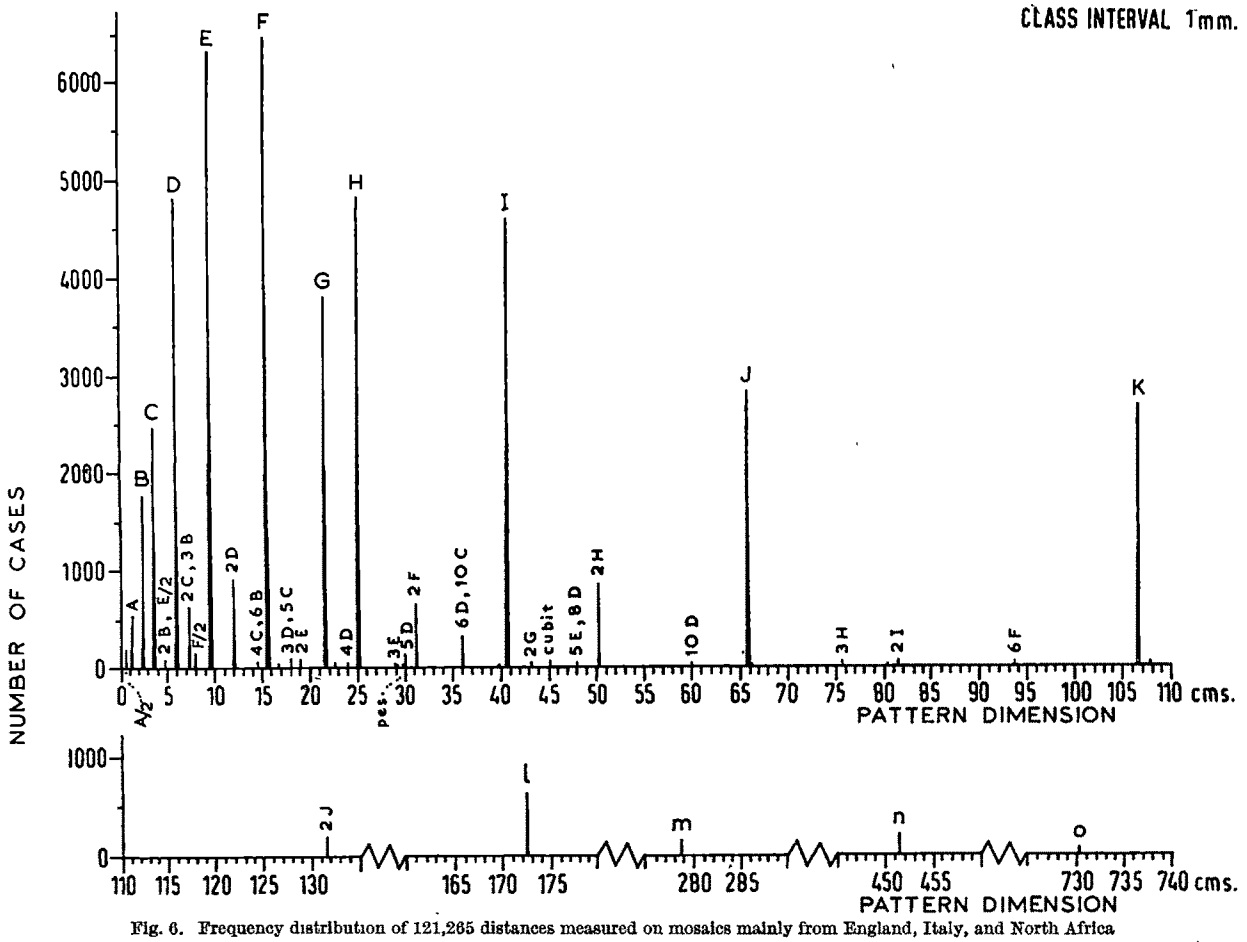

Fig. 6. Frequency distribution of 121,265 distances measured on mosaics mainly from England, Italy, and North Africa

and period of the mosaics in which such pattern sizes occurred.

A surprising result of these measurements is the general occurrence of the same absolute units, for at least a thousand years, and over a very large area. No likely relationship has been found between these Mosaic Units and known standard units of measure likely to be pertinent to the mosaic craft (its origins and development are uncertain). One might tentatively conclude that standardized tools—probably rulers—must have existed wherever classical floor-mosaics were made. Perhaps an original Mosaic Unit ruler will come to light.

Floor areas were frequently[13] fixed in terms of multiples of standard units. Because Mosaic Units are different from standard units, the mosaics would often, on completion, not have fitted the floor. This is another reason why they are smaller than the area available. The use of Mosaic Units over such a cultural and geographic extent, and for so long, suggests a practical reason for this rather than consistent subscription to a constant aesthetic. Some relation exists between the sizes of Mosaic Units and the most likely sizes for patterns, which would occur from the ways in which stones pack—that is, if one only considers common modal sizes.

Close agreement exists between the values of Mosaic Units and the easiest sizes for patterns, calculated from the hypothesis mentioned at the beginning of this article. That this may be the reason for the phenomenon of the Mosaic Units is supported by observations of the stones in adjacent rows in unpatterned mosaics. Every so often, many stones lie in line transversely through several of the rows, and the distances between such alignments frequently agree with the intervals which the hypothesis predicts. This aspect is at present being examined in a fundamental way, for it is possible that the packing hypothesis is a special case of a concept suggested here, that random disorder does not exist in reality.

If the mosaicists found, during the course of time, that their patterns tended to turn out most regular when made certain sizes, it is possible that, in order to take advantage of this, they made rulers with which to guide their construction.

It is hoped that when this thesis is published in full it will be of use in the investigation of other systems composed of aggregated varied parts. The work was supported in part by a grant from the Worshipful Company of Goldsmiths, from John Perryn's Charity, which enabled me to stay at the British School at Rome, and by two grants from University College, London. I thank Prof. R. Warwick (Guy's Hospital Medical School), Dr. H. Kalmus (University College, London), Prof. E. G. Turner and Prof. T. B. L. Webster (Institute of Classical Studies) for their help and encouragement. Construction of an automatic-studying machine for work on packing is being aided by gifts of machinery from I.B.M. and the British Broadcasting Corporation.

OBITUARIES

Dr. J. B. Goodey

PLANT and soil nematodes have attracted few zoologists and it is all the more remarkable that the Goodeys, father and son, who trained, the first partly and the second wholly, as botanists, should have become world authorities on one aspect of the subject, namely, identification and classification. Basil Goodey joined his father at Winches Farm, St. Albans, the field station of the London School of Hygiene and Tropical Medicine, about a year before the Department of Nematology moved to Rothamsted Experimental Station. Until his father's death in 1953 he was mainly concerned with plant parasitic nematodes of the genus *Ditylenchus*, but afterwards he gradually assumed his father's role, published more than sixty scientific papers describing many new species and became increasingly interested in nematode taxonomy. He also undertook the revision of his father's books. *Laboratory Methods for Work with Plant and Soil Nematodes* was revised and enlarged three times. A supplement to *The Nematode-Parasites of Plants Catalogued under their Hosts* was produced and then, with the help of Dr. Mary Franklin and Mr. D. J. Hooper, the whole was completely revised shortly before he died. His greatest contribution to nematology, however, was the complete revision in 1963 of *Soil and Freshwater Nematodes* with descriptions and re-descriptions of many new genera and a new classification of major groups.

John Basil Goodey was born at Dorridge, Warwickshire, on May 10, 1914. Like his father he was a Quaker. During the early years of the Second World War he was engaged in Quaker relief work and for several years served as Clerk to the Society of Friends in Harpenden. He was educated at City of London School and University College, London, where he took his degree in 1937 and was Quain student in botany for the next two years. From 1943 until 1947 he worked in the Oil Seeds and Weed Control Unit first in the Imperial College of Science and Technology and later in the Department of Agriculture, Oxford. In 1961 he was awarded a D.Sc. degree of the University of London for work on plant nematodes and, in 1964, was elected a Fellow of the Institute of Biology. In 1962 he lectured at Cornell University, and in 1964 assisted in a nematology course, the first of its kind in India, at the Indian Agricultural Research Institute, New Delhi, under the auspices of the Rockefeller Foundation. From 1959 he served on the editorial board of the international journal, *Nematologica*, doing much to raise the standards of taxonomic papers by publishing in that journal "Data to be Considered, Observed and, Where Possible, Reported upon when Presenting Descriptions of New Species". His illustrations of species were models of clarity and essentially diagrams without unnecessary artistic embellishment. Over the past 2 years he had become interested in numerical taxonomy and had prepared for the computer lists of characters of major groups. He was happiest advising, teaching or serving others and, because of him, many students as well as experienced nematologists came to Rothamsted to learn to identify plant nematodes, or to work on the collection there, and samples for diagnosis were received from all over the world. Visitors from abroad were also welcomed in his home where, with Mrs. Goodey, they would spend the evening in discussions ranging from politics to literature and art.

While on his way to spend 18 months in New Zealand and Australia at the invitation of the New Zealand Department of Scientific and Industrial Research, he died of a heart attack on October 30, 1965, and was buried at sea. He leaves a widow, a daughter and two granddaughters.

F. G. W. JONES

Prof. Frank Allen

FRANK ALLEN, late emeritus professor of physics at the University of Manitoba, died on November 19 at Winnipeg, Canada, aged ninety-one. Born in New Brunswick of United Empire Loyalist stock, he was a fellow schoolpupil of the late Lord Beaverbrook. Like Beaverbrook and many of his generation, he held fierce religious and political beliefs; these were only tempered by time and by his love for science.

He graduated from the University of New Brunswick in 1895 with highest honours in physics and chemistry and a Gold Medal in Latin. He was appointed high school principal the same year at the astonishingly early age of twenty-one. In five years he had saved enough money to take him to Cornell, where he took his Ph.D. in 1902 for work on physiological optics, a subject which absorbed him for the rest of his life. It might well have been otherwise, for at Cornell he became interested in Oliver Lodge's newly discovered thermionic diode. He allowed himself to be dissuaded by Nichols, his professor, from investigating the effect of adding a third, or grid, electrode. A few years later Lee de Forest did add a third electrode and promptly patented the amplifying triode valve. The era of electronics was born and de Forest made a fortune. Thereafter, Allen frequently and ruefully warned his research students to be wary of taking the advice of any professor.

In 1904 he accepted the founding chair of physics in the new University of Manitoba and remained there all his life, attaining Fellowship of the Royal Society of Canada in 1912 and honorary doctorates of both Manitoba and New Brunswick.

With an annual research budget which would be spent by a modern physics department in an afternoon, he and his small group of enthusiastic students were forced to use themselves as research equipment. He wrote some sixty substantial papers, articles and books, mostly on the sensory reflex. He confirmed the Helmholtz trichromatic theory of colour vision, and accurately quantified the Fechner law of the intensity of visual stimulus. Then he turned to the other senses and showed, one after another, that they too followed the same logarithmic law. His methods were elegant and simple: the critical frequency of repeated stimulus, the least observable increment to a given stimulus and the effect of fatigue. All the senses, auditory, tactile, pain, pressure, heat, taste and muscular response, yielded to his persistence and ingenuity. Only the sense of smell defeated him; the olfactory reflex was too delicate and sensitive for the experimental techniques available to him. He never spared himself as subject; the senses of pain and taste, in particular, demanding considerable fortitude. He made much of his apparatus with his own hands, and brought a fine sense of craftsmanship to everything he did, whether it was making an instrument, carving a turkey or chopping wood, all three of which he much enjoyed.

He constantly preached the importance of science and the excitement of discovery, while for relaxation he delighted to write and converse in Latin, Greek and Hebrew. He outlived practically all his contemporaries and, indeed, many of his research students.

He is survived by his two sons and daughter.

J. F. ALLEN

NEWS and VIEWS

The Royal Society : Vice-Presidents

The president of the Royal Society, Prof. P. M. S. Blackett, has appointed the following vice-presidents for the year ending November 30, 1966: Lord Fleck, treasurer of the Royal Society, formerly chairman of Imperial Chemical Industries, Ltd.; Prof. A. A. Miles, biological secretary of the Royal Society, director of the Lister Institute and professor of experimental pathology in the University of London; Prof. M. J. Lighthill, physical secretary of the Royal Society and Royal Society research professor at the Imperial College of Science and Technology in the University of London; Prof. H. W. Thompson, foreign secretary of the Royal Society and professor of chemistry in the Physical Chemistry Laboratory, University of Oxford.

Chemistry in the University of Edinburgh : Prof. C. Kemball, F.R.S.

Prof. C. Kemball, at present professor of physical chemistry at the Queen's University of Belfast, has been appointed to the chair of chemistry in the University of Edinburgh in succession to Prof. T. L. Cottrell, who has been appointed first Principal of the University of Stirling. Prof. Kemball will take up his appointment on August 1, 1966. He was educated at Edinburgh Academy and at Trinity College, Cambridge, where he graduated in 1943 with first-class honours in the Natural Sciences Tripos. After war-time employment by the Ministry of Aircraft Production in the Department of Colloid Science in Cambridge, he was elected a Fellow of Trinity College in 1946, holding, in addition, a demonstratorship in physical chemistry from 1951. In 1954 he was appointed to the chair of physical chemistry at the Queen's University of Belfast, where he has also served as dean of the Faculty of Science and, from 1962 until 1965, as vice-president of the University. Prof. Kemball is distinguished for his work on the mechanism of heterogeneous catalytic reactions, leading to new knowledge of the nature and reactivity of absorbed radicals on metal film. He has been a pioneer in developing new techniques for the study of absorption phenomena and catalytic activity. His interest in these fields was aroused and stimulated by his association with Sir Eric Rideal at Cambridge and with Sir Hugh Taylor at Princeton, where he spent the academic year 1946–47 as a Commonwealth Fund Fellow. Awarded in 1951 the Meldola Medal of the Royal Institute of Chemistry as the most outstanding British chemist under the age of thirty, he won the Corday-Morgan Medal and Prize of the Chemical Society for 1958, and, in 1962, was the first non-American to receive the Ipatieff Prize of the American Chemical Society. He was elected a Fellow of the Royal Society in 1965.

Headship of the Plant Pathology Division, Ministry of Agriculture, and the Chair of Mycology and Plant Pathology in the University of Belfast : Prof. R. K. McKee

Dr. McKee, principal scientific officer at the John Innes Institute, Hertford, has been appointed to the headship of the Plant Pathology Division, Ministry of Agriculture, and the chair of mycology and plant pathology in the University of Belfast. He takes up this joint post in January 1966. Robert K. McKee, a native of Northern Ireland, was educated at Campbell College, Belfast, and at Cambridge, where he was an exhibitioner of Emmanuel College. After gaining his B.A. in 1938, he went to Trinidad to the Imperial College of Tropical Agriculture, where he carried out research on witches' broom disease in cacao, and lectured in mycology until 1943. After serving 3 years in the Royal Navy as a radar officer, he was appointed to the Agricultural Research Council potato storage station, Nottingham, to investigate the control of dry rot and common scab. Here, he discovered the toxicity of solanine to micro-organisms and the influence of solanine content on disease resistance in potato tubers. While at Nottingham, he was awarded a Ph.D. by the University and, in 1956, moved to the John Innes Institute to become the pathologist in the Potato Genetics Department. He first studied the inheritance of resistance to potato virus *Y* and potato blight in wild *Solanum* species and then carried out selection experiments towards breeding new scab- and blight-resistant potato varieties. While surveying some recent collections of South American potatoes, he discovered a new virus, Andean potato latent, which is unusual among potato viruses in having spherical particles. Dr. McKee has made valuable contributions to the methodology of his subject and has also been actively interested in the biochemical basis of disease resistance and the systematic distribution of steroidal alkaloids in *Solanum*.

Ministry of Power : Advisory Council on Research and Development

The Minister of Power, Mr. F. Lee, has appointed Dr. H. M. Finniston, managing director of the International Research and Development Co., Ltd., and technical director of C. A. Parsons and Co., Ltd., to be a member of his Advisory Council on Research and Development. Also appointed to this Council is Mr. P. A. Lingard, a full-time member of the Electricity Council since March 1965.

Production Engineering Advisory Service

In a written answer in the House of Commons on December 14, 1965, the Minister of Technology, Mr. F. Cousins, stated that he had decided to set up a Production Engineering Advisory Service to help the engineering and allied industries to increase their productive efficiency. This service would cover all aspects of engineering, from the improvement of engineering design to new and improved management and production techniques, including automation. It would be available to all engineering firms and would be operated on behalf of the Ministry by the Production Engineering Research Association in conjunction with the Ministry's regional offices. Mobile demonstration and advisory units would be stationed in each region and teams would be available to visit engineering works and show designers, foremen and production staff how to use the most modern production engineering techniques. The service would begin as soon as the mobile units could be prepared and staffed, and Mr. Cousins hoped it would be in operation in all regions within 12 months. Initially it would run for 4 years at an estimated net cost to the Exchequer of about £1 million.

Careers in Engineering

In a written answer in the House of Commons on December 13, the Secretary of State for Education and Science, Mr. A. Crosland, stated that he and the Minister of Technology were aware of the desirability of encouraging more young people to enter the engineering profession. An interdepartmental Publicity Working Party on Technology and Engineering had recommended a special publicity programme which included films for exhibition in schools, a number of travelling exhibitions and a

publication on careers in technology. In 1966 the Council of Engineering Institutions would carry out, with the support of the Ministry of Technology, a major survey of the distribution, deployment, remuneration and responsibilities of professional engineers, with the view of throwing light on the nature of the work which they perform.

Ministry of Transport : Advisory Council on Road Research

In a written answer in the House of Commons on December 13 the then Minister of Transport, Mr. T. Fraser, gave the terms of reference of the Advisory Council on Road Research as being to advise the Minister of Transport on the orientation and scope of research on roads and road traffic, including the design, construction and maintenance of the road system, traffic engineering, road safety and the interaction of the technical problems with economics, and to submit reports from time to time. The chairman is Dr. F. E. Jones and the deputy-chairman Prof. W. F. Cassie. The members include Sir Edward Dodd, Prof. G. C. Drew, Col. S. M. Lovell, Drs. J. P. Bull and A. R. Collins, and Messrs. J. Armour, A. C. Durie, S. H. Grylls, W. G. Harris, M. Holmes, O. A. Kerensky, M. Law, D. J. Lyons, J. S. McNeil, A. A. Shenfield, E. C. Williams and L. H. Wilson.

Ministry of Education and Science : Home and International Commitments

In reply to questions in the House of Commons on December 16, the Secretary of State for Education and Science, Mr. A. Crosland, said that the Government had agreed to participate in the Intersecting Storage Rings Project at the Geneva Laboratory of the European Organization for Nuclear Research, which is aimed at increasing the effective power of the existing equipment, and had offered to the Organization for evaluation, though without commitment, a site in Norfolk for the construction of a 300-GeV accelerator; it had joined the International Agency for Research on Cancer, and was now preparing to participate in the initial phase of the International Biological Programme. In 1965 provision had been made for an expenditure of £53·6 million for Research Councils and other science votes.

Fast Reactor Agreement between Japan and Britain

An agreement for an exchange of information and collaboration on fast reactor research and development has now been signed by Sir William Penney, chairman of the United Kingdom Atomic Energy Authority, and Mr. Kaneo Niwa, president of the Japan Atomic Energy Research Institute. Information to be exchanged concerns design and operating experience, basic physical and chemical properties of materials for use in fast reactors, reactor physics, and operating experience with certain fuels. The agreement will be effected by means of reports and visits; assistance in carrying out research and development will be given by procurement of materials and equipment and the use of facilities. There may be exchanges of staff from time to time. The progress of the agreement will be reviewed periodically at meetings between representatives of the Authority and the Institute.

United States–Yugoslavia Exchange Programme

The U.S. National Academy of Sciences and the Council of the Academies of Yugoslavia have announced plans for a programme of exchange visits by scientists of the two countries. The agreement, which covers a 3-year period, became effective from January 1 and provides for exchanges in all the disciplines in which the two Academies are mutually competent; natural sciences, including mathematics; engineering sciences; and behavioural sciences. The new programme is flexible in its provisions for both short-term visits by individual scientists to lecture, to conduct seminars, to survey research, or to exchange professional views and, for longer stays of up to 1 year, to carry out laboratory research or investigations in the field. Visits in each direction, totalling approximately 40 man-months per annum, are provided under the programme, with no necessary matching of either the number of exchanges or the scientific fields in which they occur. In addition to its provisions for the exchange of individual scientists, the agreement provides for co-operation between the two Academies in the field of scientific publications and documentation, including the exchange of information on research institutions and programmes and mutual assistance and advice on the exchange of books and scientific literature.

Register of Research in the Human Sciences (1962–65)

The third edition of the *Register of Research in the Human Sciences (1962–65)*, compiled by the Warren Springs Laboratory of the Ministry of Technology, has recently been published (Pp. vi + 353. London: H.M.S.O., 1965. £1 17*s*. 6*d*. net). This new edition is almost twice as large as its predecessor and contains more than four times as many entries as the first edition. The *Register* has been compiled on the basis of information received from more than 300 sources, covering research in the social sciences and in those fields of medicine, engineering, law, architecture, economics, history and geography which relate to the social sciences, and information is included for the first time on research in Northern Ireland. The layout of the *Register* is unchanged—each entry containing a brief description of the research project, research workers, approximate starting and completion dates of the project, interim and final results, parties concerned with the enquiry and other information. It is regrettable that a separate name index has not been provided.

Training the Creative Scientist

Dr. G. T. Seaborg's remarks on *The Creative Scientist: His Training and His Role* (Pp. 9. Oak Ridge, Tennessee: U.S. Atomic Energy Commission, Division of Technical Information Extension, Educational Materials Section (Dept. *SS*-1), P.O. Box 62, 1963) were originally addressed to the fourteenth National Science Fair at Chicago, in May 1963, but the pamphlet in which they are now published is still highly pertinent to the present situation. Dr. Seaborg's approach may be poles asunder from that of Prof. Kuhn, but his plea for greater care and interest in teaching science in its historical context in both schools and universities is fundamentally sound. Something on the lines of his pamphlet, adapted to the conditions in Britain, could contribute materially towards filling the vacant places in university science departments and towards fostering the supply of scientists with a wider outlook and greater adaptability.

Britain and the Scientific Industrial Revolution

In his lecture, "Britain's Part in the New Scientific Industrial Revolution" (Forty-third Earl Grey Memorial Lecture delivered at the University of Newcastle upon Tyne, May 17, 1964. Pp. 19. Newcastle upon Tyne: The University, 1965. 3*s*.), Prof. J. D. Bernal is concerned with the industrial and social changes arising out of the ideas which sprang from the scientific revolution that followed the discovery of X-rays in 1896. This industrial revolution is characterized by the removal of any limitation on the supply of power, and immense changes in the speed and feasibility of communication. The utilization of the digital electronic computer, the applications of advances in genetics and molecular biology in medicine and agriculture, and what he terms the 'research revolution', have all played a part in making science the most rapidly growing human activity. This growth of science will transform the whole world, and Prof.

Bernal holds that neither Britain's scientific effort nor her industry is adequate to face the change. Besides higher expenditure on scientific research, he urges both expansion and reform in education and a determined effort to avoid waste of trained manpower.

Overcrowding in Schools

Under the title *What Chance Has Your Child?* (A Study of the Effects of Overcrowded Classes in Our Schools. Pp. 15. London: National Union of Teachers, 1965. 6*d*.), the National Union of Teachers has issued a pamphlet by Miss K. Gibberd, to which Sir Ronald Gould contributes an introduction, describing the effects of overcrowded classes in terms of the children and teachers involved. In England and Wales some 75·1 per cent of all children in primary schools are being taught in classes of thirty or more, and 17·7 per cent in classes of forty or more, while in secondary schools 51·7 per cent are being taught in classes of thirty or more. Sir Ronald Gould believes that if anything there is greater need for smaller classes in the primary schools than elsewhere. Miss Gibberd does not indulge in facile generalizations and what she writes about the frustration of both teachers and children is the more impressive. She also notes a tendency, arising out of national parsimony, to calculate rigidly the needs of a school on the basis of one teacher and one classroom to every forty children and no more of either until another forty children are added to the school roll. She emphasizes the key importance of a sufficient number of competent teachers, and her sensitive presentation of the human issues should promote the public understanding, which is the only firm foundation for directing national resources to the appropriate end.

Tracking Hurricanes

Britain is fortunately spared the terrible ravages of the giant tropical storms which may, and often do, sweep across the islands of the West Indies and the Gulf of Mexico, extending along the North American coast. The critical period of each year is from June to November, when these hurricanes, mostly born in mid-Atlantic, gather velocity and, following unpredictable, haphazard courses, roar across the Caribbean Islands and adjacent mainland, leaving death and destruction in their trail. In years past there was apparently little in the way of organized scientific study of these hurricanes, particularly as a means of forewarning people in those places likely to be in their path, in order that, given time, preparations could be made and safety measures taken accordingly. Often, tragically, there was no time, such is the speed and strength of these furious storms. To-day, tracking of hurricanes has evolved into a highly organized branch of meteorology; search planes, radar, television-equipped *Tiros* satellites, and an international communications system are used to follow and report every whirling storm of wind and rain as it develops. Broadcast bulletins give advance warning to enable residents of threatened areas to take steps to protect lives, homes and property. Public education in the behaviour of hurricanes has proved to be the best means of reducing their toll. A brief account of this vital work is contained in a short article entitled "Tracking the Hurricanes" (*The Lamp*, Standard Oil Co. (New Jersey), New York, 47, No. 3, 1965). The Esso Standard Oil S.A., Ltd., the parent company's marketing affiliate in the West Indies, the Bahamas, Bermuda, Central America and Panama, in 1964 decided to help promotion of hurricane safety in the many widely scattered islands and regions where it operates, by the preparation of a hurricane tracking map for free distribution by Esso dealers. The object of this publication was to make it possible for customers to follow broadcast storm reports, mark a hurricane's position by latitude and longitude, thus plotting its course from hour to hour. The article included information on the meaning of Weather Bureau returns, explanation of a storm's behaviour, and suggested safety precautions. The circulation of this map exceeded 200,000; newspapers also reprinted it. The article includes a small-scale reproduction, as a grim reminder, of the paths of some destructive hurricanes of the past (1938–64); this was included with the original map in question. It is noted that similar hurricane maps were made available in 1965 and presumably the same facilities will operate in future years; this is a most praiseworthy and rewarding enterprise on the part of the oil company concerned.

The Glaxo Volume

The Glaxo Volume is the title of a most attractive publication which is described as "An occasional contribution to the Science and Art of Medicine", the twenty-ninth issue of which is now available (Glaxo Laboratories, Ltd., Greenford, Middlesex. Pp. 48. 29, 1965). At the outset it is pointed out that articles in *The Glaxo Volume* are contributed by medical and other scientists, including some of the technical staff of Glaxo Laboratories, Ltd. The authors remain anonymous for professional reasons. The first article is entitled "Fears for Food" and deals briefly with the necessity of discarding the concept of what is 'natural' about our foods and diets, and of considering, in the light of modern medical and nutritional science, what is wholesome and what is safe. The question of the use of food additives is discussed; this poses the problem of how much of the food additives or residues the citizen is likely to consume in the ordinary course of events and what is going to be the effect of three, or six, or even twenty times that amount. It is pointed out that even with the present limited number of 'permitted' additives or residues, monitoring their presence or effects in human or animal foods "is a pretty forbidding task". The second article concerns "The Blood-Clotting Mechanism". This discusses what is known as the 'classical' theory (Morawitz, 1905), the 'augmented' classical theory (Owren, 1947), some information from haemophilia, opposing theories, the 'sequential' theory, evolution of the clotting mechanism, and the 'derivative' theory. This article includes some excellent explanatory diagrams in colour appropriate to the text. A third article is entitled "Pregnancy and Plumpness". The belief that pregnancy predisposes to obesity is widespread but ". . . singularly little is known about the nature of the weight gained during pregnancy or about the natural history of body weight during the childbearing years". The problem is considered under the headings of weight gains during pregnancy, physiological storage of fat, variations in the pattern and effect of age and parity on body-weight, and concludes with some practical considerations. In marked contrast is the article "Art in Bedlam", a short account of one Richard Dadd (1817–86), a painter whose imagination developed unusually during a long period in Bethlem Hospital (nicknamed 'Bedlam'); a reproduction of one of his paintings "The Fairy Feller's Master Stroke" (in colour), is shown The fifth article is "Genetics and Drug Response", considered under the subheadings: blood groups, taste testing, haemoglobin 'Zurich' and sulphonamides, *X*-chromosome gene deficiencies and acetylation of isoniazid and other drugs. This article comes to the conclusion (*inter alia*) that "Unexpectedly wide variations can occur between responses of different people to the same dose of a drug. New drugs in particular should therefore be used with appropriate caution". Finally, an amusing, if not satirical, article entitled "Men are Not Machines" brings to a close this excellent publication which one could wish was more than an occasional contribution to medical science.

Solution to Waste-handling Problems

There are many problems inherent to raw water clarification, conditioning of slimes and sludges, and other industrial and sanitary processes. Most cases, indeed, where suspended material has to be removed from aqueous

systems, demand time, research and trial for their effective resolution. A new polymeric flocculant known as 'Primafloc *C*-7' is now available in commercial quantities for such purposes and a brief account of its constitution, merits, and properties is to be found in a short article entitled, "A Solution to Waste-handling Problems" (*Rohm and Haas Reporter*, Rohm and Haas Co., Philadelphia (London, Lennig Chemicals, Ltd., 26–28, Bedford Row), 23, 5, September–October 1965). This new product is a water-soluble cationic polyelectrolyte, supplied as a free-flowing, slightly hygroscopic powder, one of the latest in a series of such compounds to be offered by Rohm and Haas. It readily dissolves in water at a concentration of 2–6 per cent; before use, this solution is normally diluted to a working concentration of about 0·1 per cent. It is claimed that, in the clarification of turbid waters, 'Primafloc *C*-7' can be used as a prime coagulant; addition of inorganic coagulants such as alum or ferric sulphate is unnecessary. Furthermore, addition of 1–10 p.p.m. of this compound, together with a suitable clay, will rapidly and effectively remove suspended solids, an advantage where restrictions preclude the use of inorganic coagulants. If inorganic coagulants are used, 'Primafloc *C*-7' (0·1–1 p.p.m.) can greatly increase floc growth and settling rates, thus improving final water clarity. Since most naturally occurring suspended particles have a negative surface charge, causing them to repel one another and remain suspended, 'Primafloc' cationic polyelectrolytes, containing as they do a larger number of positively charged sites, work on the principle of neutralizing these negative charges, causing particles to coagulate, and thus to settle. There are other 'Primafloc' polyelectrolytes available for various purposes in waste-handling problems.

Procter and Gamble, Ltd.

THE internationally known Procter and Gamble organization comprises not only the parent and subsidiary companies in the United States, but also companies operating in Belgium, Canada, France, Great Britain, Italy, Mexico, Peru, Philippines, Switzerland, Venezuela, and West Germany. The principal products manufactured by this group are the familiar retail brands of synthetic detergents, edible shortenings and margarines for the bakery trade, industrial soaps, textile brands of soap in various forms, certain building trade specialities, and other products including refined and hardened edible oils, fatty acids, glycerine, fat additives for animal feeds, etc. All these products are manufactured and sold in Great Britain by Procter and Gamble, Ltd., whose financial statement for the year ended June 30, 1965, has been published (Procter and Gamble, Ltd., *Financial Statement for the year ended 30th June 1965*. Pp. 16. Newcastle upon Tyne: Procter and Gamble, Ltd., 1965). Apart from the commendably lucid statement of the financial aspects of this company's affairs, which has previously been commented on in these columns (*Nature*, 204, 1257; 1964), this report contains much of both technical and economic interest. The emphasis in this report is on the functions and activities of those members of the Company whose task it is to buy the raw materials, goods and services needed in the course of day-to-day operations. Under the heading "Buying Better Value for Consumers" are discussed new products and new processes, the buyer's broad responsibilities, product improvement, transport and international operations. Transport is particularly emphasized in this brochure, which contains another series of most pleasing illustrations in colour of buying and shipping activities, the work of David Knight, who contributed so much to the artistic value of the 1964 statement. On the research side, a new extension of the Longbenton research laboratories has made it possible for all major research departments to be brought under one roof. The job of the Research Division is to ensure that every product is formulated to give maximum performance and appeal in its own field. One instance of this may be quoted: in the past 16 years, the Division's home laundry carried out the equivalent of 80,000 weekly washes, equal to 1,600 years of domestic washing experience for one household; its controlled test methods are based on present-day domestic washing habits as established by consumer research. It is noted that during the year under review, the Company has co-operated fully with the Monopolies Commission in their investigation of the household detergent industry.

Soils and Foundations

MOVEMENT resulting from interactions between soils and foundations was the subject of a recent publication by the Building Research Station, a note of which appeared in *Nature* (208, 1163; 1965). A further publication in the same series outlines the soil and other investigations necessary in assessing the suitability of sites for new buildings and is entitled *Soils and Foundations*: 2 (*Building Research Station Digest* (Second Series), No. 64. Pp. 6. London, H.M.S.O., 1965. 4*d*.). The need for thorough site investigation when any building work is envisaged which may be potentially vulnerable to conditions existing below ground-level is a prior charge on the project, and cannot be too strongly emphasized; this applies equally to alterations and extensions of existing work as to entirely new schemes. The comparative scarcity of building sites available for large projects, especially in built-up industrialized areas, has led to the use of sites which may have been avoided in the past for one reason or another but have now come up for serious reconsideration; in such circumstances early re-appraisal of the site is imperative, so that any special measures that may be required to deal with difficult conditions can be planned at the outset. This publication outlines the main stages to be undertaken in any investigation of site conditions; these are, first, information available off site (appeal to the local authority, Ordnance Survey maps and records from local sources for knowledge of soil and general conditions, for example, infilled ponds, ditches, streams and disused pipes). Secondly, it is necessary to undertake site reconnaissance, which should include topography, possibility of flooding, groundwater-level and vegetation as a clue to the nature of sub-soil. The third stage embraces site history, whether virgin land or a previously used site. The fourth covers soil investigations on site, which means those concerned with relatively simple observations or tests, and, where necessary, full-scale soil mechanics to determine the strengths and deformation characteristics of the soil under load and to identify conditions in which soils are otherwise susceptible to movement. *Soils and Foundations*: 2 contains a useful table of soil identification, a summary of the scope of site investigations both in plan and in depth, details of information required from any one site, and notes on sampling (use of post-hole auger, etc.). An appendix on various sources of information about any particular area concludes what is undoubtedly a most valuable guide to an often complex problem of site investigation.

Bibliography on Religion and Science

A BIBLIOGRAPHY on religion and science, compiled by A. Maltby (The Library Association. Special Subject List No. 46: *Religion and Science*. Pp. 36. London: The Library Association, 1965. 10*s*.; L.A. members, 7*s*. 6*d*.) is arranged in three sections covering, respectively, the history of the conflict between religion and science prior to the nineteenth century; the nineteenth century struggle; and the relation between religion and science in the twentieth century. Nearly 200 of the 238 entries, some of which are annotated, fall into the third section. There is an index of authors. Although the bibliography appears to be representative, the basis of selection is not stated and there is one startling omission: A. N. Whitehead.

Postgraduate Agricultural Studentships

A LIMITED number of postgraduate studentships are to be awarded by the Ministry of Agriculture, Fisheries and Food and the Department of Agriculture and Fisheries for Scotland for the academic year beginning October 1. The studentships are available in the various branches of husbandry, horticulture, farm management, agricultural or horticultural economics, agricultural or horticultural statistics, marketing, agricultural and dairy engineering (including farm mechanization and farm building), rural estate management and agricultural science. Applicants normally resident in England, Wales and Northern Ireland can obtain further information and forms of application from the Ministry of Agriculture, Fisheries and Food, Room 231A, Great Westminster House, Horseferry Road, London, S.W.1. Applicants normally resident in Scotland should apply to the Department of Agriculture and Fisheries for Scotland, Room 53, St. Andrew's House, Edinburgh, 1. The closing date for receipt of completed application forms is February 28. Awards are also available to postgraduate and post-doctoral students of agricultural science under the NATO Science Studentship and Fellowship Programme, which is intended to stimulate the exchange of students between member countries. The scheme is administered for United Kingdom students by the Science Research Council, State House, High Holborn, London, W.C.1, to which application should be made by March 1.

Medical Research Council: Industrial Psychology Research Unit

THE Industrial Psychology Research Unit of the Medical Research Council, which was formerly housed at University College, London, has now moved to the headquarters of the National Institute of Industrial Psychology, 14 Welbeck Street, London, W.1. Dr. C. B. Frisby, director of the Institute, will take over the honorary direction of the Unit from Prof. G. C. Drew. Aspects of the work of the Unit, which has been concerned with investigations of shift work, incentives, absenteeism, labour turnover and industrial accidents, will continue to appear in *Occupational Psychology*.

University News:

Birmingham

THE following appointments have been made: Dr. M. J. Chamberlain (lecturer in the Department of Experimental Pathology); Dr. G. Harris (Senior Research Fellow in the Department of Experimental Pathology); Dr. R. Jefferis (Research Fellow in the Department of Experimental Pathology).

Edinburgh

THE following appointments have been made: *Senior Lectureships*, A. M. M. Wilson (bacteriology); Dr. A. D. S. Barr (mechanical engineering); *Lectureships*, R. A. Jones (animal health); Dr. J. Godfrey (zoology).

London

DR. LEWIS WOLPERT, reader in zoology at King's College, has been appointed to the chair of Biology as applied to Medicine tenable at Middlesex Hospital Medical School. The title of professor of experimental pharmacology has been conferred on Dr. J. R. Vane in respect of his post at the Institute of Basic Medical Sciences.

Newcastle upon Tyne

T. M. FROST has been appointed lecturer in the Department of Mechanical Engineering as from January 1.

Sheffield

DR. R. J. MOFFETT has been appointed lecturer in applied mathematics.

Announcements

MR. J. P. M. BRENAN has been appointed deputy director of the Royal Botanic Gardens, Kew, and keeper of the herbarium and library, as from December 1, on the retirement of Dr. C. E. Hubbard.

THE Council of the Institute of Metals has made the following awards: *Institute of Metals (Platinum) Medal for 1966*, to Prof. F. A. Forward, Privy Council Office, Ottawa, for his services to the non-ferrous metal industries; *Rosenhain Medal for 1966*, to Mr. A. Cibula, British Non-ferrous Metals Research Association, for his contributions in the field of physical metallurgy.

APPLICATIONS are invited from members of the Plastics Institute for the award of the Novadel Prize for 1965–66. The Prize, awarded annually by the Plastics Institute and worth 100 guineas, will be given for the best essay or report received before September 30, 1966, on some aspect of the reinforced plastics industry. Further information can be obtained from the Secretary, the Plastics Institute, 6 Mandeville Place, London, W.1.

A SEMINAR on "Planning and Organization of Science Research in Developing Countries", arranged by the Science of Science Foundation, will be held at the Ciba Foundation on March 14. Further information can be obtained from the Science of Science Foundation, c/o the Ciba Foundation, 41 Portland Place, London, W.1.

A SYMPOSIUM on "Non-elastic Processes in the Mantle", arranged by the Upper Mantle Committee of the International Union of Geodesy and Geophysics, will be held in the University of Newcastle upon Tyne, during February 21–25. Further information can be obtained from Dr. D. C. Tozer, School of Physics, University of Newcastle upon Tyne.

THE annual general meeting of the North of England Section of the Society for Analytical Chemistry will be held in Manchester on January 29. The meeting will be followed by the presentation and discussion of a paper entitled "Thermal Analysis with reference to Inorganic Hydrates". Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

A SHORT course on "Recent Developments in Polymer Technology" will be held at the Bradford Institute of Technology during February 25–26. Lectures will include aspects of newer polymers; die design; polymer reinforcement; testing for end-use performance; developments in epoxide and polyurethane polymers. Further information and forms of application can be obtained from the Registrar, Bradford Institute of Technology, Bradford 7.

A CONFERENCE on "Recent Progress in Physical Optics" will be held in Paris during May 2–7, in association with the seventh general assembly of the International Commission for Optics. Further information can be obtained from the Secrétariat du Congrès CIO 7, Institut d'Optique, 3 Boulevard Pasteur, Paris 15. Funds have been made available for travel grants for: (*a*) 'young scientists'; and (*b*) other scientific workers, to attend the conference. Applications for such grants should be made, before January 20, to the Chairman of the National Sub-committee for Optics, the Royal Society, Burlington House, London, W.1.

ADDENDUM. In the article entitled "Stimulation of the Uptake of Water and Ions by Indolyl-3-acetic Acid: its Dependence on Nucleic Acid and Protein Synthesis", by R. Mitra and S. P. Sen, which appeared on p. 861 of the August 21, 1965, issue of *Nature*, the explanations of the symbols used in the figures were omitted and are as follows:

Fig. 1. ●, IAA; ○, actinomycin *D*.
Fig. 2. ○, IAA; △, porphyromycin; ●, actinomycin *D*.
Fig. 3. ○, IAA, ●, actinomycin *D*.

THE USE OF MANPOWER

ONCE more the annual conference of the Institute of Personnel Management has been concerned with an issue of vital importance to the national well-being. Held at Harrogate during October 7–9, the conference was attended by more than 1,000 members and visitors from all parts of the world and considered how Britain should make the best use of manpower.

In an opening address, the Minister of Labour suggested ways in which productivity could be improved to achieve the 25 per cent increase required in the National Plan, without the 400,000 extra workers who would appear to be required and who will not be forthcoming. First, he suggested increased investment in labour-saving plant and machinery. Innovations, such as numerically controlled machine-tools, automatic welding techniques and automatic lathes, are all helping the engineering industry to produce more goods with proportionately fewer workers. Automation is being introduced to the coal mines, where considerable increases in productivity are being achieved through the use of remotely controlled faces. Computers are being used for many routine office jobs and an increasing number of firms appreciate that computers can also be used for advanced design work and for production control.

Secondly, if we are to take full advantage of technological progress, it is inevitable that some industries will decline, and release workers. Other industries will expand and will need these workers. There should be no obstacles to this movement. Firms which keep workers they do not need help neither themselves nor the country, nor—in the long run—the workers themselves.

Thirdly, the deployment and use of our available manpower resources should be critically examined. This is equally important at all levels—on an industry basis and in the individual firm, as well as over the economy as a whole. A number of industries have already estimated possible increases in output per head if various obstacles to the efficient use of labour can be overcome. In a number of other industries, management organizations and unions are together examining the measures which must be undertaken to ensure a more effective use of manpower. It is at the level of each factory and office that the problem must finally be tackled.

What are the obstacles to achieving greater efficiency in the use of labour? A great deal is heard about restrictive practices such as unnecessarily high manning scales, restrictions on the introduction of new machinery or working methods, on the entry of trainees, and insistence on outmoded demarcations. They cannot be tolerated in the battle for economic objectives. They must be vigorously tackled by both management and unions. In recent months there has been a significant increase in the number of agreements between management and the unions allowing for a greater flexibility of working and the removal of practices which impede efficiency.

Deliberate restrictive practices are, however, only a part of the problem. A much greater problem is the ready acceptance of traditional ways of doing things. Industry must be prepared to reappraise objectives and the means of achieving them. The initiative for this rests primarily with management although joint productivity committees also have a most important part to play. A well-developed system of joint consultation is essential to the orderly development of progressive ideas.

There is also need not only for rigorous scrutiny of the deployment of manpower at present, but for a forward look. The report on the metal industries published recently by the Manpower Research Unit of the Ministry of Labour showed that fewer than one in four of the firms approached made manpower forecasts for more than two years ahead. Half the firms appeared to do no forecasting at all. A firm that wants to develop a systematic training programme—any firm that is planning to expand its production or introduce major technical changes—cannot afford to neglect the vital element of manpower in its forward planning.

The Government itself recognizes that a firm cannot plan ahead if it feels at the mercy of outside forces, not knowing what the Government and the firms which are its customers and suppliers intend to do. This is one of the reasons why the National Plan has been published.

The Government also recognizes that it has an obligation to help men to adapt their skills or to learn new skills. During the past two years, the number of places in Government Training Centres has been more than doubled and the number of centres has been increased from 13 to 30, providing, by the end of 1965, 6,000 training places. A further expansion, bringing the number of centres to 38 and places to 8,000, has been announced. When all the expansion plans have been completed, the centres will be capable of producing some 15,000 trained men a year.

But this is only a small contribution to the training that is needed, and industry must still play by far the greatest part in this. The Industrial Training Act was passed to encourage employers to accept this responsibility. Nine boards are now established and by early 1966 the boards will cover some 8 million employees—one-third of British industry. The Government must also do everything possible to minimize hardship caused by necessary changes of employment.

A further obstacle to growth is the present regional imbalance in the economy. While firms in the South and Midlands are plagued by shortages of labour, unemployment in areas like Scotland, Wales and the North is still well above the national average. Financial assistance is being given to firms which build or expand factories in Development Districts and control is being exercised over the issue of Industrial Development Certificates in areas where the demand for labour is high.

Mr. Gunter was followed by D. A. C. Dewdney, vice-chairman of the National Board for Prices, Incomes and Productivity, who stated that responsibility for employment in British industry has been much too fragmentary. One part of an organization decides that it needs so many people of such-and-such grades to do a particular kind of work. Then another part of the organization does the hiring, looks after the workpeople when they have been employed, and probably carries out the negotiations with the unions. The processes of employing are thus divorced from those of deciding what the employed person is actually supposed to do, and management all too rarely asks itself the really fundamental question—why am I employing this man at all? It is extraordinary that this attitude should have persisted into the post-war years, when the problems have not been those of shortages of work but shortages of labour. This is reflected in the replies of a number of industries to the Government while it was preparing the National Plan, when many industries admitted to having under-employed labour resources. Such a situation will have to be radically changed if national ambitions for economic growth are to be fulfilled. Productivity is at the heart of the policy of which the National Board for Prices, Incomes and Productivity is the instrument. Productivity is one of the three complementary and inseparable themes of the policy,

all three components of which have been steadily neglected in the past. This neglect represents an idleness of habit which it is the purpose of the policy, and the Board, to change.

Productivity cannot be separated from the problems of prices and incomes and, in the short run, our present position requires that demands for increases in incomes be moderated. If they are not moderated through the exercise of self-discipline, other factors will take over and moderation will be imposed. The usual alternative to self-restraint has been found to be a rise in unemployment. The only other method of restoring equilibrium is strict physical control.

It has become increasingly clear that the problems with which we are faced are both economic and social. The diagnosis is a matter of economics, but the solution is much more social and educational.

The main role of the Board should be as a part of the educational process. Its reports should not merely be admonitory but constructive. A second requirement for the reports is that they should be of as wide a general significance as possible.

Mr. Dewdney also made it clear that in order to implement the prices and incomes policy with institutions as they now stand, management must take the initiative in trying to balance the expectation of the people of Britain for better things against our ability to earn them. Such initiative will be welcomed by the Trade Unions.

Sir John Hunter, chairman of the Central Training Council, discussed the role of training in a technological age. He indicated that the most important steps in the approach by management to training policy are:

(1) Training is an integral and essential part of management function. Top management must therefore be closely involved in development of training policy; and basic responsibility for implementation of policy is a matter for line management—not to be devolved on training staff, and conveniently forgotten.

(2) A survey of training requirements should be undertaken. This involves analysing the responsibility, skill and knowledge of different jobs, and an examination of the extent to which staff discharge them inadequately. Are such problems as high turnover, production bottle-necks and lack of promotable staff due to lack of training?

(3) Management needs to be able to call on expert advice and assistance in analysing job and training requirements, and implementing training programmes.

(4) Is training effective? There should be a regular check on training programmes to ensure that staff get what help they need to carry out their responsibilities satisfactorily.

Among the many problems to be faced is that of management development. It is generally recognized that far too many firms adopt a haphazard approach to management recruitment, development and succession. This is not merely a matter of prestige courses: there must be a planned programme which starts with selection of potential managers, and includes relevant and challenging experience on the job, regular reviews of progress and development of specific required skills and knowledge through carefully chosen courses (internal and external).

A second key problem is the need for training officers. The Boards will have to make a big effort to train considerable numbers of training advisers and training officers capable of providing firms with expert support in the development and implementation of training policy. This effort will involve introductory courses for postgraduate students and for people with suitable industrial experience, arrangements to enable relatively new or inexperienced training officers to gain experience in firms under the supervision of a senior training officer, specialist courses in technique and particular subjects for those who are already training officers, and advanced courses to enable experienced training officers to study new methods and undertake research.

The role of the universities in a technological age was outlined by Sir John Cockcroft, Master of Churchill College, Cambridge, who, after indicating the country's great lack of and need for technologists, suggested that there are different varieties of technologists, a broad spectrum requiring different training. There are, first of all, the technologists whose major role is to force the pace of technological change. Their work is predominantly intellectual and requires a deep knowledge of science. They require a strong scientific base in their undergraduate training and good postgraduate training. The second broad group of technologists are those who design and build engineering systems and make them work. Good design engineers are the most scarce of all categories and the role of the university in helping to produce them has been the subject of a recent enquiry, on behalf of the Department of Scientific and Industrial Research, chaired by G. B. R. Fielden. In the evidence given to the Committee, there was no consensus of opinion about how, or to what stage, design should be taught in the education and training of an engineer, and a large number of approaches to the problems are being tried in universities and colleges.

The Committee came to the conclusion that the 'sandwich' course is the most suitable preparation for a career as a professional design engineer. This was the type of course first adopted by the Colleges of Advanced Technology. The Committee, however, felt that it was essential that the period spent in industry by these students should be tested on what they learned during their industrial training. An alternative to the 'sandwich' course is for an engineering student entering a university to spend a year in industry before his entry, and to spend part of one long vacation in a works. In this way he will obtain a better three-dimensional feeling for the equipment he will be hearing about in the more analytical lectures. The Fielden Committee also supported experiments in teaching design at postgraduate levels, which are under way in the University of Cambridge and Imperial College. Manchester College of Science and Technology is also carrying out advanced training in machine tool design, and the College of Aeronautics is giving training in design of aircraft and aero-engine industries.

In order to teach design, it is essential that the teachers have had some personal experience of design work in industry, and since the best designers obtain salaries in industry far higher than the universities can offer, it is important that universities should obtain the services of industrial designers on a part-time basis by appointing them as extraordinary or visiting professors, readers or lecturers.

Sir John also examined the way in which the universities link up with industry to carry out research projects and to provide suitable courses in management education. The latter was discussed more fully in a sectional meeting when A. F. Earle, director of the London Business School, described the philosophy on which the School is being founded and the types of courses which it is planned to commence in the coming year. There will be a twelve-week course for men aged 28–35 in middle management positions, one of six weeks' duration for men of 35 years upwards in more senior management work, and a postgraduate course of two years' duration leading to a masters' degree designed for university graduates within one or two years of having completed their first degrees in any subject. The post-experience courses will be strenuous and will be aimed at the cultivation of analytical powers and widening the acquaintance of the students with business problems beyond their range of experience. The postgraduate course will not produce a ready-made manager—that requires extensive on-the-job experience and maturing personal qualities—but it should ensure a man with broad analytical powers and business knowledge which should enable him to travel up the manage-

ment ladder more quickly and to a greater height than would otherwise be the case.

In another sectional meeting R. Lahnhager, director of the Swedish Council for Personnel Administration, provided information about the way Sweden encourages mobility of labour. Much emphasis is placed on the relocation of industry itself and the use of investment funds to stimulate this.

In a provocative paper on the role of the personnel manager in technical change, Prof. Lupton of the University of Leeds indicated that, in the attempt simultaneously to maximize welfare and technical and economic efficiency, certain administrative techniques have been developed and are widely used in large organizations with well-developed personnel functions. He suggests that this is to put the cart before the horse. Management should decide whether there are any alternatives which might, while offering high technical advantages, also minimize the adverse social and psychological consequences. Or it might well be advantageous, if there is time to work out the possible social and psychological consequences of a number of alternative ways of introducing change, to discuss these with the people who are going to be involved, and their representatives.

All this implies the presence, when decisions are being made about technical change, of someone with expert knowledge of the organization as a social system, and who is aware of the complexities and subtleties of the relationship between technology and organization structure. Such a person will be able to predict more accurately than others the effects of projected changes in technique. The final course of action will then be based not only on economic and engineering data and methods of analysis, but on social and psychological data and their analysis, and will be a choice which satisfies all three criteria. To perform this additional function adequately demands an expertise to be learned in addition to the skills already demanded from the personnel manager.

H. Clegg of Nuffield College, Oxford, discussed the significance of wage drift in relation to an incomes policy. Wage drift can undermine an incomes policy in two ways. Incomes policies invariably attempt to control wages and salaries through the settlement of wage rates and salary rates. But rates are not incomes. Earnings are incomes: and if earnings rise faster than rates through a process of 'drift', to that extent incomes policy is ineffective. Drift is also uneven in its incidence. To some workers it can build up a pressure of resentment among the less-fortunate who demand compensating adjustments of rates. To meet these demands means further departures from the policy; to refuse them may lead to an explosion which could destroy it.

But can the drift be controlled? There is talk now of putting statutory authority behind an incomes policy, but an examination of the elements which go into drift is enough to show that this would not be easy. Quite apart from the question of sanctions, the controls would have to apply to overtime, to the various systems of payment by results, to job evaluation schemes, to promotion and up-grading and so on.

To foresee whether wage drift will become a serious obstacle to the success of incomes policy in Britain, we would have to know whether the policy is going to establish its grip on rates of salaries and wages. As yet, it has not got this far, but some of the cases which have come before the Prices and Incomes Board have directed their attention to the problem of drift, and these give some indication of the way they may try to deal with drift if that stage is reached. If the Prices and Incomes Board were to encourage a view that drift is permissible wherever it is accompanied by an equivalent rate of increase in productivity, it could lead an incomes policy sadly astray.

A more discriminating approach to the problem of mobility of labour was suggested by Dr. Hilda R. Kahn, senior lecturer in the Department of Social Administration, University of Hull. Some immobility is an entirely natural phenomenon in an affluent society. When the alternative was near-starvation, people could be expected to be almost infinitely mobile. But when a country has reached an advanced stage of socio-economic development —providing reasonable living standards, as well as a welfare state, for most—a certain reluctance to uproot oneself is a natural consequence. And it is perfectly legitimate for a society to opt for some immobility in preference to faster economic growth, provided it does not simultaneously insist on paying itself the higher income which faster growth would have made possible, but which its preference for immobility has not.

Nor is the British population nearly as immobile as has often been assumed. Thus, major changes have occurred during the post-war period in the size of important industries such as agriculture, mining, textiles and distribution; there are between two and three million job-changes each year in manufacturing industry alone; and a considerable amount of inter-regional migration has likewise taken place in recent years. Much of the two-way traffic between regions, however, has merely the effect of cancelling itself out, while some of it is actually harmful in that it has produced excessive congestion in certain parts of the country—costly in both social and economic terms. Similarly, an uncritical emphasis on mobility may accelerate mere labour turnover, and the crucial problem remains of reconciling the twin desiderata of good workplace relations and mobility. All this suggests that it is 'purposive mobility', rather than mobility as such, which policy must seek to encourage.

The aim of a mobility policy should be to seek to achieve the optimum distribution of the country's manpower through the guidance of school-leavers and the voluntary mobility of adults to the greatest possible extent. Apart from the many measures in kind which this entails—in the sphere of housing and re-training, for example—it may pay us to evolve, in addition, a system of substantial cash bonuses, to accrue to workers prepared to move where they are wanted. In view of the insistence on the maintenance of traditional relativities which has become so prominent a feature of post-war collective bargaining, it is doubtful whether we shall ever get a wage structure sufficiently flexible to further the cause of 'purposive mobility'. The proposed payments would therefore have to be operated by the Ministry of Labour via a drastic extension of its present Resettlement Transfer and analogous schemes Such 'mobility bonuses' might be used to aid all forms of desirable re-deployment, and would be alike more acceptable, more effective and quite possibly also less costly than redundancy. Such a system could also claim to be wholly fair, since it would specifically accrue to those serving the national interest.

Finally, Prof. T. Malm, of the Schools of Business Administration, University of California, showed very clearly the need for a new type of personnel administration to serve the needs of rapidly changing industry. In Britain and the United States as well as elsewhere, enterprises have been affected by varying degrees and forms of mechanization, automation and computerization. While most are still far from 'full automation', executives and workers at all levels have been seriously affected—for better or worse—by new products and processes, and by reorganization of the enterprise, the work group, or the individual job, resulting from technological change. All too often, the personnel officer has not participated fully in planning for the implementation of automation or electronic data processing, only to be called on later to 'put out fires' when human and organizational stresses and strains make clear the need for improved manpower programmes and policies. While personnel and industrial relations specialists have been leaders in 'human relations', in general they have lagged in their appreciation and application of operations research and management

science. Much needs to be done to improve the analysis of personnel policies and practices; the personnel officer needs fuller understanding of and participation in operational research and management studies to solve his own problems more effectively, and to contribute more positively to planning and decision-making, to administration and management in the enterprise as a whole.

T. H. Hawkins

PREPARATION AND STANDARDIZATION OF ISOTOPIC TARGETS AND FOILS

STABLE and radioactive isotopic films and foils of precise composition and dimensions are needed as targets for a variety of particle accelerators for nuclear data measurements; accurately defined films of α-active actinides are also needed as fission standards for reactors. Such standard targets are made in a number of laboratories in different countries and there was a clear need for closer co-ordination with the users in order to relate the limits of chemical purity and dimensional tolerance desirable to those practically attainable. To meet this need and also to promote an interchange of ideas and techniques a seminar was held at Harwell, Didcot, during October 20–21, 1965. The hosts were the Electromagnetic Separation Group of the Atomic Energy Research Establishment (A.E.R.E.) and the Special Techniques Section of the Nuclear Physics Division of the Atomic Weapons Research Establishment (A.W.R.E.).

The seminar, of about seventy scientists, was strongly supported by the Central Bureau of Nuclear Measurements of Euratom, Geel, Belgium, and the isotopic Target Preparation Centre of Oak Ridge National Laboratory (O.R.N.L.), Tennessee. Participants from laboratories in eight other countries also contributed to the 30 papers and the discussions.

Isotopic targets, which may be required on backings or self-supported, generally range in thickness from a few μg/cm² to several mg/cm². A wide variety of chemical techniques such as vacuum evaporation, electrodeposition and electrospraying, and metallurgical methods are used, but problems arise owing to the small amounts of expensive isotopic material available, the risks of isotopic contamination and the need for high chemical purity and exactly known thicknesses. Chemical conversions and purifications on the sub-gram scale may have to precede the target-making process.

During the first day the meeting considered the problems involved in these methods, means of improving process efficiencies and the effects of impurities. G. H. Debus of the Geel Laboratory emphasized the difficulties involved in obtaining exact and realistic specifications from users, in preparing and transporting samples, and obtaining from users adequate comments on the behaviour of the targets which would help future preparations. Other contributions from the Geel Laboratory discussed non-uniformity of deposits and isotopic fractionation during evaporation. G. T. Arnison of A.W.R.E. analysed the experience gained using electron bombardment techniques instead of resistance heating for vacuum evaporation. The description by W. Parker of the Chalmers University of Technology, Gothenburg, of the novel method of 'molecular plating' from organic solutions, which appears especially useful for making actinide targets, excited much interest. Experience with established methods for making α-active sources was reviewed by Mrs. Glover of A.E.R.E. and J. Champion of the French Atomic Energy Commission.

For many applications unbacked targets are desired, and several laboratories use metallurgical techniques to make isotopic metallic foils of thickness down to below 1 mg/cm². The end-product of electromagnetic isotope separation is normally the oxide, and methods of efficiently converting small quantities of the valuable isotopes to the metal were described. A range of foils of the isotopes of the rare earth metals, reactive alkaline earth metals and some of the actinides has been prepared by simultaneous reduction-distillation followed by rolling or evaporation at O.R.N.L. Some of these were shown by E. H. Kobisk, who also considered the merits of ultra-high vacuum techniques as a means of obtaining high purities. The techniques used at the Argonne National Laboratory for rolling films down to thicknesses of a few microns and at Geel for high-frequency levitation melting and evaporation were described. This latter method avoids contamination by crucible material and can be used for metallic samples of 3–100 mg. J. B. Reynolds of A.E.R.E. listed the thin stable isotope metallic foils now made at Harwell by rolling techniques and showed how the deformities and thickness contours in a rolled foil had been measured by attenuation of 5-MeV α-particles. The problems of preparing targets by very small-scale electroplating were discussed by several speakers.

The second half of the meeting was concerned with measurement and standardization. F. A. Howe, A.W.R.E., introduced the topic with a critical survey of the non-destructive methods for determination of film thickness which were applicable to nuclear targets. Methods used at Geel for precise standardization of the chemical and physical properties of targets were reviewed by H. Moret and K. F. Lauer and some specific procedures were described by other speakers. This aspect of thin-film preparation will undoubtedly receive increased attention in the future, and the first seminar on the subject was particularly useful in making the participants aware of the many causes of errors which can exist in the determination of purity, uniformity and thickness of isotopic targets. Both makers and users will undoubtedly be more cautious in the future and will understand each other's problems better. More efforts will be made to introduce monitors to follow the continuous build-up of targets and to control and measure the chemical and physical characteristics of the films and foils.

Copies of the seminar programme and abstracts and, later, the record of the proceedings can be obtained from the following address: Electromagnetic Separation Group, Atomic Energy Research Establishment, Harwell, Didcot, Berkshire.

M. L. Smith

THE NATIONAL INSTITUTE OF OCEANOGRAPHY

THE National Oceanographic Council met for the last time on October 20, 1965, and decided to petition the Queen to withdraw the Royal Charter granted in 1950. This was the final stage of the change-over of the responsibility for the National Institute of Oceanography from the National Oceanographic Council to the recently formed Natural Environment Research Council. Mr. J. P. W. Mallalieu, Parliamentary Under-Secretary of State for the Royal Navy and chairman of the National Oceanographic Council, while thanking the Council for their work over

the past 15 years in promoting the study of oceanography in Britain, referred to the growing public recognition of the importance of oceanography.

During the Second World War, very much as a consequence of the remarkable work on waves carried out by Dr. Deacon's group at the Admiralty Research Laboratory at Teddington, it was felt by many people that there should be a more concerted attack in Britain on research into the physics of the sea, and eventually, in 1949, after discussion between the Advisory Council on Scientific Policy and various Government departments the National Institute of Oceanography came into being with Dr. G. E. R. Deacon as director—the Royal Charter being granted to the National Oceanographic Council in the following year. The whole scheme provided for: (1) A Royal Charter incorporating a National Oceanographic Council with the object of advancing the science of oceanography in all its aspects, under the chairmanship of the Civil Lord of the Admiralty, and consisting of representatives of Government departments, the learned societies, the universities and those Governments of the Commonwealth that might be expected to give financial support. (2) An executive committee to implement the policy of the Council. (3) A National Institute of Oceanography to carry out the work of the Council.

Over the past 16 years the money has been provided more or less in equal proportion by the Development Commission and by the Admiralty, and there have been welcome but relatively small contributions from various Commonwealth countries. The income in 1949–50 was just over £100,000, in 1963–64 some £400,000. The nucleus for the investigation of the physics of the sea was Dr. Deacon's wave group; the nucleus of the biology department was the long-existing Discovery Investigations.

The National Oceanographic Council held its final meeting at the National Institute of Oceanography in Wormley, Surrey, and the occasion was marked by a display of exhibits illustrating the work. A press conference was held, chaired by Mr. R. E. Prentice, Minister of State for Education and Science, assisted by Dr. Deacon and by Prof. M. J. Lighthill, the chairman of the Oceanography and Fisheries Committee of the Natural Environment Research Council. Awareness on the part of the public was reflected in the emphasis which many of the exhibits placed on the user, particularly one showing over 120 enquiries from civil engineers, port authorities, etc., who have consulted the Institute in recent years for help about wave conditions and who need advice, data or instruments. Such knowledge of waves is essential to those who build and operate ships, design hovercraft, drill for oil, build ports and other coastal installations, and also to those who attempt to control coastal erosion. This display particularly illustrated the statement of the director, Dr. Deacon, that "The Institute's main purpose is to improve understanding of the basic physical, chemical and biological processes that govern all events in the ocean, and, while taking every opportunity to increase knowledge, to help as much as possible in applying it". For many years the wave group at the National Institute of Oceanography has been recognized as second to none in the world both in the study of the theory and statistics of waves and in the design of instruments for collecting measurements. The practical value of such academic research has become increasingly apparent to those who consult the National Institute of Oceanography. One major wave project in recent years has been the design of a series of buoys to measure the direction in which waves are travelling, the most recent design being a cloverleaf buoy which measures the pitch and roll of three floats held at the corners of an equilateral triangle. The direction of alignment of the buoy and the vertical acceleration at the centre of the triangle are also measured. The buoy and the ship are linked by a 26-core cable for carrying electrical power to the buoy and for bringing back reference signals and outputs to a multichannel recorder and data logger. From these records the directional spectrum of the sea waves can be computed. These results are of importance both to wave theoreticians and to the British Ship Research Association for ship motion studies. That pure research can result in wave forecasting which may save a ship time in crossing the Atlantic, or otherwise improve its efficiency, is a vindication of the purpose of the Institute in studying fundamental problems of the ocean.

Another basic problem is the study of deep circulation of the ocean, with its concomitant idea of the transfer of energy from one part of the ocean to another. Since their development at this Institute ten years ago, neutrally buoyant floats have been used to measure currents at great depths in the sea and have radically changed our ideas about the movement of the deep water. The deep currents have been found to be faster and more variable than had been supposed—fast enough to have practical implications for problems of waste disposal in the deep sea and for the design of deep moorings. These variable currents may play an important part in the general circulation of the ocean, similar to that of depressions and waves in the atmospheric circulation. One display representing examples of the deep current observations in the North Atlantic Ocean showed a fast south-flowing current close to the continental slope off North America. In mid-ocean, average speeds of 10 cm/sec at great depths were found and there was evidence of eddies some 100 km across. A narrow streak of water was discovered travelling at nearly 1 knot at 4,000 m. It also appeared that the currents at such a depth were faster than those at mid-depth (2,000 m) and moved in a more nearly meridional direction.

Much of the information about deep-water masses and their movements is obtained by the classical and still essential method of making observations at hydrographic stations, samples of water being collected at various depths with simultaneous temperature recordings, and this was part of the required international survey of the physical oceanography of the Indian Ocean. A part of the hydrographic work of the third cruise of the R.R.S. *Discovery* in 1964 during the International Indian Ocean Expedition was shown by a display of sections of salinity, oxygen and temperature at different seasons along 58° E. Besides the usual water-sampling and net hauls on stations in the Indian Ocean, relative currents were measured using propeller-type current meters in the near-surface water. Two of the most striking features were the equatorial undercurrent and the Somali current, which were both particularly well developed at the time they were investigated.

Another phenomenon associated with the Somali current, recorded as flowing north-east at nearly 7 knots, was the exceptionally cold coastal water. The association of recently dead fish with this upwelling was remarked on in the display of the Institute's biological section as was the upwelling from a different cause off the Arabian coast, investigated particularly in its association with the return of nutrients from the deep water to the surface. This was one aspect of a prominent part of the biological research, the investigation of the fertility of the oceans. Aspects of the organic cycle investigated at the Institute include photosynthesis, the growth of phytoplankton and its dependence on nutrients and chlorophyll, and the taxonomy and distribution of zooplankton, which has been investigated mainly by sampling and recently by echo-sounding. The R.R.S. *Discovery*, the main tool of the Institute, is at present at sea in the North Atlantic on a biological cruise, co-operating with visiting scientists from the United States, in an attempt to use underwater sound as a method to study the distribution of marine animals. At all times from the period of the Discovery Investigations to the present some members of the biological group have investigated certain animals in detail, most notably the common food of Antarctic

whales, *Euphausia superba*, which was the work of the late J. W. S. Marr. One of the most active investigations to-day is that of the squid, known as the diet of sperm whales, but also one of the most numerous and widely distributed animal groups in the sea. The Whale Research Unit showed exhibits representing its work with the biology of the larger species of whale of commercial importance, the blue, fin, sei and humpback whales and the sperm whale; as in the days of the Discovery Investigations the immediate purpose is to provide scientific information to help in the regulation of the whaling industry, but in the long run to aid the conservation of whales. Most of the work of the Whale Research Unit is therefore concerned with the distribution and migration, breeding cycles, feeding and population structures of these large species of whales.

Associated with the hydrographical and biological work is the work of the chemists (the 306 hydrographic stations on the third cruise of the R.R.S. *Discovery* resulted in about 8,000 water samples on which some 27,000 analyses were made while at sea). On show at the Institute were two particular projects in chemical oceanography, one concerned with a study of the major constituents and nutrients in sea-water, and the other concerned with certain related physical properties, such as electrical conductivity and density.

The three-dimensional and time-varying complexity of the ocean might make investigation of the sea-floor seem comparatively straightforward, but time variations can occur there as well. One exhibit showed that skilled interpretation of sonar records can indicate the transport path of sediments on the continental shelf in waters around the British Isles. Another exhibit of a detailed investigation of a part of the deep sea-floor showed how a turbidity current, formed from land-derived material accumulating on the edge of the continental shelf and precipitated by some catastrophe down the continental slope, may have levelled out an abyssal plain by deposition of sediments in the Bay of Biscay and then eroded a connecting channel to a lower abyssal plain west of Portugal. Such dynamic sea-floor studies are unusual, the greater part of the work being on relatively stationary features now known from the painstaking accumulation of echo-sounding records (involving the design at this Institute of a deep sea 'precision' echo-sounder with an accuracy of 1 fathom in 3,000 fathoms) together with photographs of the deep sea-floor made with a National Institute of Oceanography underwater camera. These show such various phenomena as long ripples formed by bottom currents, boulders covered by a coating rich in manganese, steep slopes in channels and on sea mounts and possible basaltic lavas from the Mid-Atlantic ridge. Cores are obtained from both the deep and shallow sea-floors, and further geological information on faults, folding and possible lithological structure of the sea-bed in shallow waters is obtained from the interpretation of sonar records. (It is evident that this shallow-water geology is of interest to exploratory oil companies.) One of the projects recently started at this Institute is the development of a geological long-range sonar for use in deep water.

The National Institute of Oceanography took an active part in the sea-floor studies of the International Indian Ocean Expedition. On all three cruises a continuous echo-sounding record was obtained; the second cruise was particularly concerned with the geophysics of the sea-floor and has helped to answer questions about the formation of mid-ocean ridges and their relation to continental drift. One exhibit showed the possible development of the Gulf of Aden as a result of the splitting away of the Arabian Peninsula from the African continent some 20 million years ago. In a sense, the Indian Ocean work was a profitable digression from the work in the Atlantic. A contoured bathymetric chart of the north-east Atlantic compiled from soundings collected in the Hydrographic Department of the Navy (many of them taken by the R.R.S. *Discovery II* and the R.R.S. *Discovery*) showed clearly the structure of the Mid-Atlantic ridge and its median valley, the complexity of the continental shelf, and the recently explored deeps in a line with, and some four hundred miles west of, the north coast of Spain. This chart also amply demonstrates how it might profitably be used for navigation in conjunction with a precision echo-sounder. In itself, as it now stands, it could be of considerable use, involving possibly large financial savings, to those who lay cables across the sea-floor.

Much of the work at the National Institute of Oceanography is unique, particularly the electronic analogue model of the North Sea, which takes into account such variables as the topography of the sea-floor and the wind pattern, and which can predict storm surges with a reliability depending on the accuracy of the weather forecast. This is but one more instance of what was very evident in most of the exhibits, the application to-day of work which some years ago was of academic interest only.

Many of the exhibits showed that, as yet, many projects are necessarily incomplete; much of the work is as yet unpublished; the gear is constantly being improved; the data obtained, despite the use of computers, prove all but intractable in quantity to the very few scientists who wish to use them, and who are yet aware that these very observations are pitifully few in relation to the size of the ocean. The most urgent need is for more people to tackle the present problems, let alone those problems which will become apparent as more gradually becomes known about the ocean. Necessarily, most of the exhibits showed the work of the past 16 years, but some included indications of that planned or hoped for in the future, such as the thermistor chain, an instrument which should be particularly useful for measuring internal waves from ships underway at speeds up to 12 knots, and depths up to 2,000 ft. The temperature-sensing units will be towed at 50 ft. or 100 ft. intervals on a single-core double-armoured cable. It is hoped also to do more work on the results of the two seismograph stations, one at Wormley and one at Haslemere, and by analysing the six outputs from these stations, to obtain the two-dimensional spectrum of microseisms at any instant of time; this will give information as to the direction of arrival of the microseisms. Their relationship to sea-waves generated in storm centres has already been clearly demonstrated. More information, too, can be obtained from the pressure telemeter designed for use on the edge of the continental shelf, this instrument having been planned to measure the very small pressure fluctuations on the ocean floor caused by the passage of surface waves overhead.

Other exhibits, more complete in themselves and distinct in their applications, ranged from the simple devices (such as jelly bottles for measuring currents, especially at the bottom, which are of particular interest to fishermen and civil engineers) to the sophistication of 'vorticity waves'. It is suggested by theory that if a mass of fluid such as the sea or atmosphere is rotating nearly uniformly an unusual type of wave motion can be projected through the fluid. A model was demonstrated showing such vorticity waves set up in water in a rotating cylindrical vessel.

When the Royal Charter was granted in 1950 there were thirteen listed objects for which the Council was established and incorporated; the first, and necessarily foremost, of these was "to advance the science of oceanography in all its aspects", and the engineering section of the Institute, in addition to designing and making the prototypes of almost all the instruments used at the Institute, both in the laboratory and at sea, has provided instruments and equipment to other laboratories throughout the world. Much of the gear is required in too small numbers to be produced commercially and in addition there is already in the Institute an accumulated knowledge of the difficulties caused by high pressure at great depths in the ocean

and by the corrosive properties of sea-water. About forty projects were displayed as exhibits by the engineering section both as instruments and by working drawings, out of some 120 designed in the past sixteen years. Some of the more recent instruments have been briefly referred to here. The stabilized narrow-beam transducer is at present being used in the R.R.S. *Discovery*; this is part of a 36-kc/s underwater acoustic echo-ranger used for work on fish-detection problems and marine geological investigations. The axis of the acoustic beam is perpendicular to the fore-and-aft line of the ship and may be rotated from the horizontal to the downward vertical. Gyro stabilization is provided against the roll of the ship; beam width and side lobe patterns are adjustable. The range is about 800 yd. and scanning is achieved by steering the ship past the features to be investigated. A more recent project is the towed vehicle, which houses a transducer array for the long-range geological slanting sonar briefly mentioned here as being intended for use in deep water, which will work at a much lower frequency and will necessarily be larger than the sonar used in shallow water. It is intended that the vehicle will be towed at a depth of about 400 ft. and, in order to obtain adequate signal levels for the sound scattered back by the sea-floor, each of the 144 transducer elements will transmit 400 W of acoustic power. In connexion with the thermistor chain a helical traversing capstan is being developed as the traction member of a deep-sea hoist for handling faired electric cables. The capstan is so constructed that the cable advances across its surface with a purely rolling action, free of slipping or sideplay; there are no unbalanced forces to cause the path to be altered.

Yet another stated object of the Royal Charter was to collect and maintain an oceanographic library and, starting in 1953 with the welcome nuclei of earlier collections, the National Institute of Oceanography Library has now grown to be one of the major oceanographic libraries, containing about 3,500 text-books, 25,000 reprints and 7,000 unpublished reports all cross-indexed for easy reference, together with an annual intake of about 400 periodicals. There is a specialized collection of charts and atlases and a fine collection of scientific reports of oceanographic expeditions. The publications of the Institute, the *Collected Reprints* and *Discovery Reports*, are distributed on a world-wide basis, preferably with an exchange arrangement In a year the library lends some 3,000 publications, about 2,500 to scientists at the Institute and the others to many outside libraries.

The work of the Institute over the past 16 years was represented by these exhibits; the general line for the future was discussed at the press conference. It was reassuring to hear from Mr. Prentice that both the growth and continuity of the present work of the Institute would be maintained under the Natural Environment Research Council and encouraging to hear Prof. Lighthill comment on the fact that, although little money had been spent on the National Institute of Oceanography, yet the return had been good value; the amount of money spent on research is not necessarily in direct proportion to the results.

MARY SWALLOW

INSECT BEHAVIOUR

THE Royal Entomological Society of London continued its series of biennial symposia by organizing a meeting on "Insect Behaviour" which was held at the Imperial College of Science and Technology, London, during September 23–24, 1965. The meeting was opened by Mr. E. O. Pearson, the president of the Society, who pointed out that the objective of this series of symposia was to provide authoritative surveys of recent work in the chosen field for the information of entomologists generally, and the very high attendance at this meeting emphasized that these symposia fulfil a real need.

Prof. Birukow (Gottingen) spoke on orientation behaviour and factors which influence it. This particular aspect of insect behaviour is engaging the attention of several German entomologists, and Prof. Birukow was able to indicate the way in which past attempts at the systematization of the subject contrasted with more recent approaches such as those of Jander. He described the capacities and physiological mechanisms of lower levels of orientation behaviour (the so-called baso-taxes) and pointed out that higher orientation behaviour may have evolved from these. The variability noted in orientation behaviour results principally from adaptive variability which ensures that an animal can never become 'a slave to its own orientation mechanisms'. Insect orientation behaviour can be adjusted by the interaction of innate and learned patterns, but in complex behaviour it is rarely possible to discriminate between these two sources. Prof. Birukow gave details of his interesting work on light orientation in *Calandra granaria*, which is affected by biological rhythms and meteorological factors.

Dr. P. S. Corbet (Ottawa) gave an account of the role of rhythms in insect behaviour, and from this wide field took as his main theme the factors which influence field periodicities. Particularly valuable were his clear definitions of the terms used to describe periodic behaviour and his elucidation of the relationships between them. He pointed out that the causal analysis of field periodicities in terms of their endogenous and exogenous components had been neglected because integration of field and laboratory work on periodic behaviour had seldom been attempted. He underlined the need for investigations of the periodicity of single processes in the laboratory under controlled conditions and also in Nature, preferably in several situations. He particularly emphasized the need for entomologists to recognize the pervasiveness of rhythmicity as an experimental variable. He instanced the response to sex pheromones, the amount of body protein and the intensity of virus transmission as processes under control of circadian rhythms which, therefore, show different values at different times of day and night. He suggested that a description of any such process should properly include an account of its periodicity, particularly when this affects its measurement or detection.

Dr. P. T. Haskell (London) discussed flight behaviour, first mentioning factors inhibiting or limiting to insect flight, particularly the effect of wind on height of flight and orientation. He went on to outline the general aspects of flight behaviour in respect of food-seeking, homing and territorial flight, defence and predator avoidance, courtship and mating, oviposition and migration and dispersal. He pointed out that there seem to be certain basic patterns which are utilized in different types of behaviour such as, for example, food-seeking and oviposition, which pose the same fundamental problem to the insect, that of homing on a target. He described recent work on mechanisms involved in anemotactic behaviour released by olfactory stimuli, which are important in relation to mating, food and oviposition behaviour, and queried theoretical deductions which supposedly rule out tropotactic orientation to an odour source.

Prof. V. G. Dethier (Pennsylvania) dealt with feeding behaviour and pointed out that in the past decades the emphasis in this field of investigation had altered from description to an investigation of mechanisms. He examined the present-day controversies as to whether

insect relationship to food plants is dictated by token or nutrient stimuli, whether oligophagy is based on attraction or repulsion and whether taste or smell is more important. Behavioural, and particularly physiological, experiments seem to indicate that all these factors are involved. The inflow of data to the central nervous system relating to stimulation by food plant substances is complex, and hence neither the mechanism of discrimination nor the basis of preference can be a simple one. Prof. Dethier pointed out that the regulation of the initiation, termination and frequency of feeding had received less attention than the problem of selection. In some insects, for example the fly, the process is driven by sensory input and is terminated by sensory adaptation, while the frequency of feeding is controlled by an as yet unknown mechanism; on the other hand, in other insects such as the locust, endogenous central activity appears to influence the initiation of feeding.

Dr. A. Manning (Edinburgh) described sexual behaviour and defined it as "specialized behaviour patterns which form the normal preliminaries to mating". He pointed out that elaborate sexual behaviour occurs in some insects but not in others and raised the problem of 'female coyness'. He considered three possible functions of courtship: appeasement and synchronization, physiological maturation, and sexual isolation, and concluded that various combinations of the foregoing functions must have been involved in the evolution of 'female coyness'. He felt that a direct origin of the movements used in courtship from modified pre-copulation movements was often plausible, and pointed out that the ritualism of insect sexual behaviour had followed a course very similar to that found in vertebrates. As to the organization of sexual behaviour, he emphasized that the data were so meagre that little generalization could be made, but that sexual behaviour seems to depend more on the sex of the brain than on that of the lower centres.

Dr. J. D. Carthy (London) spoke on insect communication, which could be said to occur whenever a sensory signal caused a change in the behaviour of an animal. He pointed out that in most cases the receiver is informed of the physiological state, the sex, the species and often the position of the sender, that the language is often private to the species and that dialects may occur which are specific to a group of individuals in a neighbourhood. He examined the range and type of visual, acoustic, tactile and chemical communication and brought forward examples showing how these may be combined to increase the total sum of information passed.

Prof. E. O. Wilson (Harvard), in dealing with the behaviour of social insects, deliberately minimized the functional aspects of this behaviour in order to pay close attention to theoretical considerations of its evolution. In examining its origin, he supported the view of Hamilton that true sociality, mostly limited to the Hymenoptera, had arisen because of the haplo-diploidy prevalent in that order, which, since it resulted in greater genetic similarity between siblings than between parents and offspring, favoured the development of altruistic behaviour. Sociality in the termites, he felt, was associated with obligatory protozoan symbiosis, thus taking the view that true sociality was made possible through pre-adaptations which themselves had nothing to do with sociality. Prof. Wilson went on to examine fitness in insect societies and indicated, for example, that worker inefficiency, including mass behaviour that is the opposite of social facilitation, is widespread in the social insects and yet makes a positive contribution to colony fitness. On balance, however, he concluded that the question of altruism above the individual level remains open.

The final paper was given by Dr. J. S. Kennedy (Cambridge) and the arrangements for this were of an experimental nature in that Dr. Kennedy was asked to talk on "Some Outstanding Questions in Insect Behaviour", drawing largely on points raised by the preceding speakers and thus promoting wide-ranging general discussion to end the symposium. Dr. Kennedy treated four main topics: the origin of social behaviour, communication and 'female coyness', orientation behaviour, and the control of responsiveness. As regards the origins of social behaviour Dr. Kennedy disagreed with Prof. Wilson and suggested that the long-standing theory of parental care as the basis of social behaviour was still adequate. The ensuing lively discussion touched on the value of parental care, the influence of food-sharing, the significance of symbiosis and the evolution of altruistic and selfish behaviour. On balance, while it was conceded that the phenomena of haplo-diploidy and symbiosis may have played some part, parental care won the day as being likely to afford a sufficient basis for the evolution of sociality.

As regards 'female coyness', Dr. Kennedy asked if this was widespread and enquired whether 'male coyness' was also involved, and whether in any case the term was not a misinterpretation of the delaying function of the behaviour which may be necessary so that both males and females can complete internal processes essential to mating. The discussion emphasized the paucity of data on the subject, although the interesting suggestion was made that there was selective value to the behaviour if it was considered as an extension to normal pre-copulatory communication which establishes specific recognition.

On orientation, Dr. Kennedy asked whether the system of Jander did in fact correspond to the 'natural structure' of the behaviour; the discussion did not elucidate this point and served to emphasize the continuing lack of any adequate structure for the classification of insect behaviour.

The final problem discussed by Dr. Kennedy was the control of responsiveness in insects in various behavioural situations, and raised the important issue of the separation of endogenous activity, or 'drive', from reflex activity—the stimulus-response system. The general tenor of the discussion was that the past approach to this problem, based on an 'either–or' choice of these two concepts, had been misleading; the actual system probably involved characteristics of both.

All the papers and the ensuing discussions are to be published shortly in a fully bound volume by the Royal Entomological Society.

P. T. Haskell

FOREST NURSERIES

Forest nurseries became important in British forest practice with the introduction of exotic conifers in the latter part of the eighteenth century for large-scale reforestation work on private estates. But they assumed even greater importance after the creation of the Forestry Commission in 1919 with its declared policy of afforestation. At the present time the plant requirements of the State forest service and of private estates and commercial enterprises are enormous and nursery practice has become a scientific matter. This has developed greatly in the past twenty years. Before that, nurseries were mainly the agricultural type where fertility was maintained by farmyard manure in some cases but mainly by ploughing-in green crops and the use of fallows and rotational practice. However, it was found that the best conditions were not being obtained for growing coniferous seedlings. These were required in greater quantities than ever and in less time than the usual 3–4 years to produce a plant suitable for afforestation purposes. Some experimental work had been done by the Forestry Commission, but in 1944 it

was decided to set up a "Sub-Committee on Nutritional Problems in Tree Nurseries" the terms of reference of which were "to assess the problems underlying the nutrition of forest trees in nurseries and to suggest any desirable extensions already in progress".

The account of the work carried out between 1945 and 1962 by a joint research effort between staff of the Rothamsted Experimental Station and the Research Branch of the Forestry Commission is embodied in *Forestry Commission Bulletin* No. 37 *.

Volume 1 comprises the text and the main tables and Volume 2 contains detailed supporting tables, but this second volume is not needed for reading the first. The initial volume contains three main parts. First, there is a historical account of nursery practice in Britain since the 1920's. The objects and scope of the investigation are defined and notes are provided on sites and experimental methods. The second part, and by far the largest, is concerned with seed-bed experiments and these are well described and supported by adequate tables. The third part deals with experimental work on transplants and this required extension experiments.

Histories of individual nursery sites and notes on sylvicultural techniques are included in the appendix and there are useful supplementary papers on microfauna and microflora. There are eight pages of coloured plates and they can only be described as superb. They bring out in a most certain way what each plate is meant to show. Indeed, the whole publication maintains that high standard associated with Forestry Commission bulletins.

Volume 2 will have a limited demand, but Volume 1 is a valuable contribution to the understanding of forest nursery problems and to the improvement of techniques in raising young trees for afforestation and re-forestation purposes. As planting is likely to be the means most used for many years to come in regenerating Britain's forests, it is obvious that good forest nursery practice is of the greatest importance. C. J. TAYLOR

PERUGIA UNIVERSITY MEDICAL SCHOOL

NEW LECTURE HALL OF PATHOLOGY

By PROF. LUCIO SEVERI

Director, Institute of Morbid Anatomy

ON June 27, 1965, Lord Florey, president of the Royal Society of London and Provost of Queen's College, Oxford, opened the new Lecture Hall of Pathology in Perugia, Monteluce. At the same time he delivered the first Cesare Massari lecture entitled "The Anatomy and Physiology of Small Blood Vessels".

The ceremony was attended by the Magnifico Rettore of Perugia University, members of the Perugia University Medical School, participants in the third Perugia quadrennial international conference on cancer ("Lung Tumours in Animals"), and other distinguished guests from many Italian universities.

Science in Perugia

It Italy, as elsewhere, there is an ever-growing and deeply felt concern about the training of scientists and technologists. In Perugia, scientists and technologists are graduating in large numbers, certainly in greater numbers than at any other time. These numbers, however, are not satisfactory, since scientists and technologists comprise only about one-third of the student population—the lowest point of a progressive percentage decrease over the past 26 years. The numbers of students in pharmacy, agriculture and veterinary medicine are not increasing, although these faculties are traditional in the University of Perugia; however, the Faculty of Science, founded during the academic year 1951–52, is steadily developing. It is difficult to give figures, as classification is, to some extent, subjective, especially in a university where everyone has his own ideas on how disciplines should be grouped together. Nevertheless, Table 1 gives some figures.

Of the figures given in Table 1, scientists represent the proportions shown in Table 2.

Medicine in Perugia

The Perugia University Medical School is fortunate: although it is situated within the city boundaries, it lies on Monteluce hill (1,500 ft. above sea-level) facing east; it dominates the valley of the Tiber and looks on to Assisi and the Appenines (snow-capped for the greater part of the year). The development of medical studies has followed a normal pattern, as can be seen from Table 3.

The Medical School has steadily expanded its facilities since the end of the Second World War. New buildings have been provided for those departments dealing with general pathology and morbid anatomy, orthopaedics, paediatrics (with a Poliomyelitis Department), surgery and dentistry. A large six-storeyed block has been built for the Institutes of Biology, Physiology, Anatomy, Pharmacology, Forensic Medicine and Hygiene. Small lecture rooms have been set aside for seminars and tutorials in each Institute and there is a large common lecture hall sufficient for 300 students. Probably the most interesting development in the field of research in the Perugia Medical School has been the growth of the Division of Cancer

Table 1. TOTAL STUDENTS (ALL SUBJECTS)*

	Undergraduate	Postgraduate	Total
1938–39	615	—	615
1949–50	2,558	—	2,558
1954–55	2,606	86	2,692
1959–60	3,906	289	4,195
1964–65	6,130	248	6,378

* The student enrolment figures quoted in the text were taken from the University of Perugia Year Books for the academic years 1938–39, 1949–50, 1954–55, 1959–60 and 1964–65.

Table 2

	I	II	III	Total scientists	Total students	Total scientists expressed as a percentage of total students
1938–39	—	263	201	464	615	75·4

Research[1] which is housed at Monteluce, although its personnel are involved only in a tenuous way with the University.

Medical teaching requires both large and small lecture theatres, but this need has not yet been met at Perugia.

The New Lecture Hall of Pathology

In Italian medical schools, the teaching of pathology is divided into two parts: general pathology for students in their second and third years, and morbid anatomy (or pathological anatomy, including pathological histology) for students in their fourth and fifth years.

In Perugia, the two teaching programmes have always had a common lecture hall, and during the period from 1927–28 until 1949–50, this was in the old Institute of Morbid Anatomy and seated only about 40; then, when the two Institutes transferred in 1950–51 to a new building where they have so far been located, they used a lecture hall which accommodated about 135, but this was demolished in the spring of 1964.

The Lecture Hall of Pathology has now been rebuilt between a retaining wall (about 15 metres high) and the back wall of the Institutes of General Pathology and Morbid Anatomy. Its ground plan is in the form of a trapezium with its shorter parallel side abutting on to the Institutes. The floor level of the new Hall corresponds to that of the old one, and to the ground-floor level of the Institute of Morbid Anatomy.

The building has three storeys including a basement, and between the ground and first floors is the lecture hall itself. This opens off the main entrance of the Institutes, from which run two lateral corridors. These lead to the hall and, below the hall, to the dressing-rooms and toilets. The right-hand corridor also leads to the outside on the east; the one on the left ends in a stairway which leads into the garden on the west side and basement.

At the back of the area below the hall are two stairways, which ascend to the first floor where the hall can be entered from two sides. From a stairway on the left a narrow corridor gives access to the large central projection room and four small cabins, two on either side; these can be used for simultaneous translation. The hall is 20·4 m long, and the dais area projects into the old building for 3·6 m. The 340 seats are placed in 12 ascending rows, with one row at floor level, and rise steeply in three large blocks—the two side blocks being at a slight angle to the central one. Two stairways divide the side and centre blocks. The top (13th) row is 4·6 m from floor level.

Lighting within the hall is both artificial and natural; daylight comes in from six windows in the eastern wall and from four in the western; on the first floor, the two windows at the entrance to the hall give a panoramic view of the city of Perugia. Total or partial darkening is controlled electrically from the dais or from the projection room. Enclosed in the wall near the dais there is hot and cold water. Behind the table is a large blackboard with indirect lighting. Microphone and loud-speaker equipment, as well as simultaneous translation equipment, have been installed, and the hall is centrally heated. The screen is lowered electrically from the ceiling just in front of the dais area (a solution which is not entirely satisfactory, but is dictated by considerations of projection). Good acoustics are assured by a ceiling consisting of differently inclined planes, lined with sound-absorbing material.

The lecture hall is not used for dissection, which is undertaken in special rooms and in another small tutorial room. Corpses are brought from all departments to the central area of the basement by means of an underground passage. In the western part is the post-mortem section.

The building is a concrete-cased steel-framed structure, faced with grey-coloured plaster. However, the two lateral corridors are built of vertical metal frames so as to permit a continuous series of windows. The roof is umbrella-shaped, with beams converging towards the retaining wall; particular care was required in its construction because of the thrust of the beams from above on the opposite wall of the building.

The foundations were laid on piles because the soil on the site consists of light clay with an admixture of sand. The total surface covered by the building is about 550 m².

This new Lecture Hall of Pathology is the largest, the most modern and the best-equipped of its kind in Italy. The building was designed by Prof. G. Nicolosi, Rome, and the construction was carried out by Fioroni Brothers, Perugia, under the direction of Dr. G. Tosti, Perugia.

INSTABILITY OF SOME OF THE PRODUCTS FORMED BY THE ACTION OF *N*-METHYL-*N*-NITROSOURETHANE ON CYSTEINE *IN VITRO*. ROLE OF NEIGHBOURING GROUPS IN ENZYMATIC AND CARCINOGENIC ACTION

By Dr. R. SCHOENTAL

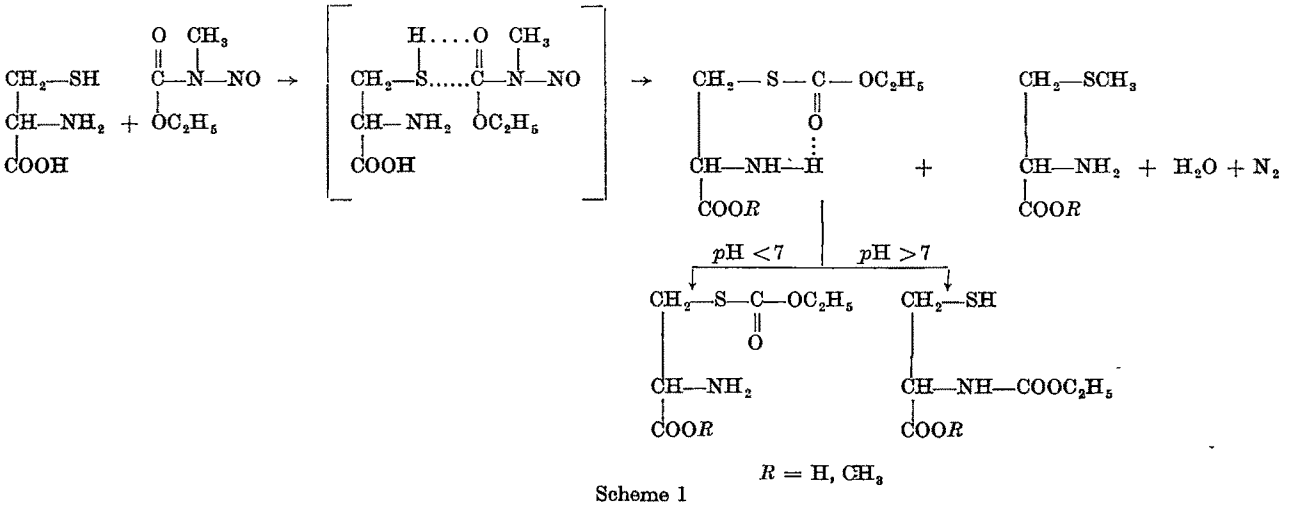
Toxicology Research Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey

IT has been suspected for more than a quarter of a century that sulphydryl-groups play a part in the carcinogenic process. Though much work has been devoted to their estimation in conjunction with the treatment with carcinogenic agents, and to other aspects of this problem, no clear picture emerged in this connexion. Recently, however, new developments in the field of carcinogenesis once more focused attention on the role of sulphydryls, mainly the fact that certain newly discovered carcinogens interact *in vitro* with free thiol groups without the need of enzymes. This is the case of 4-nitroquinoline-*N*-oxide[1], β-propiolactone[2], *N*-hydroxyurethane[3] and *N*-alkyl-*N*-nitrosourethanes[4].

Free sulphydryl-groups are known to be very reactive; their competition factor has been reported to be 1,000 times higher than that of terminal amino- or hydroxy-groups[5]. They can interact with carbonyl-groups, the more readily when these are activated, for example, by the presence of *N*-alkyl-*N*-nitroso-groups, as is the case with *N*-alkyl-*N*-nitrosourethanes and related carcinogens.

Detailed investigations of the reaction between cysteine and *N*-methyl-*N*-nitrosourethane (MNU)[6] disclosed that the reaction proceeds readily at room temperature with evolution of nitrogen and complicating mixtures of products are formed. The reaction appears to proceed according to Scheme 1. At *p*H 6·5 the main products were *S*-ethoxycarbonylcysteine and its methylester and *S*-methylcysteine and its methylester. The esters are unstable and hydrolyse on standing even at neutral *p*H. *S*-ethoxycarbonylcysteine itself is very sensitive to alkali. Dilute ammonia or phosphate buffer *p*H 8·0 at

room temperature transforms it rapidly into *N*-ethoxycarbonylcysteine, with the restoration of a free sulphydryl group. The latter is then capable of interaction either with a second molecule of MNU (to form *S,N*-diethoxycarbonylcysteine), or with the 'active methylene' released on the disruption of the MNU molecule (to form *N*-ethoxycarbonyl-*S*-methyl-cysteine) or with any other sulphydryl reagents, such as ethylmaleimide. The isomerization of the *S*-ethoxycarbonylcysteine to the *N*-derivative proceeds even in almost neutral, aqueous solutions (*p*H 7·2) when these are left at room temperature for a few days.



In cysteine, the sulphydryl- and the amino-groups are in close proximity and the isomerization is probably facilitated by a hydrogen-bonded cyclic intermediate.

Isomerization by alkali of *S*-substituted cysteines to their *N*-isomers have been observed in the case of the *S*-(2,4-dinitrophenyl)-derivative[7] and of the *S*-carbobenzoxy-derivative[8]. However, *S*-ethoxycarbonylcysteine isomerizes even more readily, even at the physiological range of *p*H, and its behaviour may serve to illustrate the action of sulphydryl enzymes.

Several thiol groups are usually present, as cysteine residues, in almost any molecule of a protein and enzyme. Sulphydryl groups exert several roles in cellular functions; they regulate the oxido-reduction potential, determine the folding and the tertiary configuration of proteins and only very few are actually involved in the catalytic activity of enzymes. For the latter role, the presence of appropriate neighbouring groups appears to be essential, such that would enable them to form cyclic intermediates with the substrate.

Sulphydryl groups, owing to their great reactivity, will interact more readily than other groups with certain substrates, but in order to be able to do so repeatedly, as is required for catalytic action, they must be able to hand over the substrate to other neighbouring groups and be restored for further action. *S*-ethoxycarbonylcysteine can be considered a prototype of such behaviour; its ethoxycarbonyl group migrates readily from the sulphur to the adjacent amino group with which it could not have reacted directly. It is possible that this isomerization proceeds by way of a hydrogen-bonded cyclic intermediate such as shown in Scheme 1. The restored thiol is then free for further action.

Among the products of the reaction between MNU and cysteine *in vitro* *S*-ethoxycarbonylcysteine methyl ester and *S*-methylcysteine methyl ester were present[6]. As mentioned already, these esters were unstable and hydrolysed readily even at neutral *p*H and at room temperature, probably due to the intra-molecular proximity of the amino- to the ester-group. Neighbouring groups are known sometimes to exert striking effects on the rate of hydrolysis of esters; for example, the β-benzyl ester of *N*-carbobenzyloxy-L-aspartyl-L-serylamide has been shown to hydrolyse 10^7 times faster than benzyl-propionate[16]. The authors suggested that this might be due to the ease of formation of a cyclic imide intermediate in the former. Other neighbouring groups, such as hydroxy-[17] or carbonyl-[18], increase also the rate of hydrolysis of esters. In some esterases and certain hydrolytic enzymes the 'active site' is known to be associated with the hydroxyl of serine residues, possibly in conjunction with histidyl-imidazoles[19]. Among the enzymes, in which the amino-

Scheme 1

In the case of the sulphydryl enzyme, creatine phosphokinase, Rabin and Watts[9] observed that the rate of the reaction of iodoacetate or iodoacetamide with the 'active sulphydryl' was independent of *p*H in the range 6·0–10·0. They suggested that this might be due to hydrogen bonding between the thiol and a basic group in its proximity, possibly the imidazole of a histidine residue. The reaction rate of these alkylating agents with thiol groups of several other enzymes, namely, of phosphoglucomutase[10], arginine kinase[11] and yeast alcohol dehydrogenase[12–14], has since then been reported to be independent of *p*H changes in a wide range.

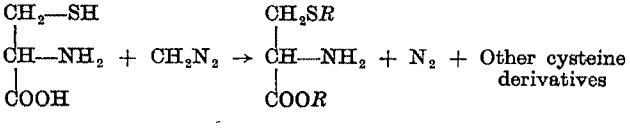
In yeast alcohol dehydrogenase a histidine residue is actually adjacent to the cysteine bearing the 'active thiol' (according to Harris—quoted by Thomson *et al.*[15]), but in some of the other –SH enzymes this is not the case. As pointed out by Rabin, the basic group does not necessarily need to be present on the amino-acid bound by a peptide bond to the cysteine residue; it could be brought into close proximity in the tri-dimensional structure of the enzyme by appropriate folding of the protein.

acid sequence of the 'action site' has been established, a histidine-residue has been found to be adjacent to the 'active' serine-residue on the same peptide chain in phosphoglucomutase[20]; but in others, for example chymotrypsin or trypsin[21,22], histidine-residues are present only in remote parts of the peptide chain, yet by appropriate folding of the protein they might be brought into close proximity to the serinyl-hydroxyl. On denaturation, when the peptide chains unfold, the reactivity of the 'active' serinyl-hydroxyl is usually lost[19].

During physiological activity the attachment of a substrate to, and the release of the product from, the active sites of enzyme proceed continuously, but when a foreign chemical is mistaken for a normal substrate it might remain irreversibly attached to the active or its neighbouring group and inactivate the enzyme.

The typical sulphydryl reagents, such as ethylmaleimide, block probably all accessible thiols—hence their high toxicity and lethal effects on cells. Chemical carcinogens, however, appear capable of inducing more specific changes in the cell, such as are compatible with its survival, and

lead to progressively more pronounced changes until a tumour erupts months or years later.



Many of the known chemical carcinogens have the following characteristics: (*a*) they can interact with sulphydryls without the need of enzymes, and (*b*) they are, or become, through metabolic transformation, bi- (or multi-) functional agents.

This is *par excellence* the case of *N*-methyl-*N*-nitrosourethane, one of the most effective carcinogens and capable of inducing cancer even with a single dose. This efficacy may be related to its acting as a multi-functional agent. When it reacts with sulphydryls it yields both an ethoxycarbonyl-group and an 'active methylene'; hence it is capable of concurrent substitution of several reactive groups. This is of obvious importance in cellular reactions, which mainly take place on surfaces. The probability of concerted multi-point substitution by mono-functional agents is obviously much smaller.

The sulphydryls which react with MNU and form *S*-ethoxy-carbonyl-derivatives will not necessarily remain substituted; as mentioned already, the ethoxycarbonyl-group can be shifted readily to a vicinal amino-group when the *p*H changes only slightly and a free thiol is restored. However, when the 'active alkylene', released *in statu nascendi* from the decomposing MNU, reacts with thiols to form thioethers or alkylene bridges, such derivatives will be more stable. If such derivatives were formed *in vivo*, especially on the structural proteins or enzymes, they could profoundly alter their tertiary conformations and the oxido-reductive or catalytic activity The part which such alkylations may play in the carcinogenic process is still not clear.

Many alkylating agents show no, or only marginal, carcinogenic activity, notably the alkyl halides and dialkylsulphates (Dr. P. N. Magee, personal communication). Physiological methylations whether of *C*-, *N*-, *O*-, or *S*- are essential biochemical processes in the cell. The difference between the various 'alkylating' agents may depend on the 'site' which is alkylated. Bulky 'active methionine' (*S*-adenosyl-methionine) or alkylating agents requiring enzymes will alkylate easily accessible reactive groups, while small 'active alkylenes', like those derived from the carcinogenic *N*-alkyl-*N*-nitrosourethanes or diazoalkanes, may be able to reach some of the more sterically hindered or 'buried' sulphydryls and other reactive groups. Indeed, the size of the 'active alkylene' may be related to the efficacy of the parent compound. It has been reported that MNU is more toxic and more mutagenic than ENU for the fungus, *Colletotrichum coccodes*[23]. In rats, given single doses of these two homologues by stomach tube, MNU proved to be about six times more acutely toxic than ENU (Schoental, unpublished results). Both compounds induced stomach tumours, but it is too early to evaluate their relative efficacy in this respect. However, an additional factor must also be considered: ENU reacts with thiol compounds more sluggishly than MNU, and the rate of evolution of the 'active ethylene' would be slower.

It could be argued that the role of *S*-ethoxycarbonyl-substitution should not be disregarded in the carcinogenic action of alkylnitrosourethanes in view of the carcinogenic activity shown by urethane itself. However, even in the case of urethane it has been reported[3] that *S*-ethyl-cysteine, as well as *S*-ethoxycarbonylcysteine, was present among the products of hydrolysis of a mercapturic acid-fraction obtained from the urine of rats dosed with this

R = H, CH_3

Scheme 2

compound. This suggests that ethyl-groups may be released from urethane. In experiments *in vitro* using cysteine (or glutathione), *S*-methyl-derivatives and their methyl esters, were the common products formed with both carcinogens, diazomethane (Scheme 2) and *N*-methyl-*N*-nitrosourethane (Scheme 1), and this would suggest that attention should be focused on products formed by the action of 'active alkylenes' with cell constituents, when considering the mechanism of carcinogenesis.

It is conceivable that in the intact cell some of the guanine-imidazoles of nucleic acids are in close proximity to certain thiols of structural proteins. It may be significant that isolated nucleic acids persistently retain small amounts of proteinaceous material, and that in certain cases it would appear that sulphur is involved in the links between the nucleic acids and the residual proteins[24]. Thus, it has been reported[25]: "The requirement of the reducing agent (β-mercaptoethanol) used for the isolation of DNA from mammalian sperm suggests the presence of a special sulphur-containing linkage between DNA (or a component attached thereto) in the sperm nucleus and the protein coat, cleavage of which is necessary before the nucleic acid can be released". It is also known that it is exceedingly difficult to free ribonucleic acids isolated from various viruses from residual proteinaceous materials[26]. In the case of the infective RNA isolated from ^{35}S-labelled tobacco-mosaic virus (TMV), the RNA retained ^{35}S-radioactivity, connected presumably with the residual protein, which resisted various attempts at its removal[27]. Eventually, treatment of the TMV–RNA with bentonite reduced the protein content to trace quantities[28]. The difficulties of obtaining nucleic acids free from small amounts of proteins (or peptides) would indicate the existence of, perhaps co-valent, bonds between proteins and nucleic acids. In this connexion, the fact that the majority of co-enzymes are either nucleotides or have structures analogous to nucleotides is of particular interest. Whether the sites where a protein-thiol is linked or close to a nucleic acid-imidazole represent the 'sensitive centres' involved in the carcinogenic action of alkyl-nitrosourethanes and of some other chemical carcinogens requires further investigation.

The carcinogenic *N*-methyl-*N*-nitrosourethane reacts *in vitro*, at room temperature, with thiol groups, with the evolution of nitrogen, and effects multi-point substitutions. With cysteine, at *p*H 6·0–7·0, *S*-ethoxycarbonylcysteine and *S*-methylcysteine and their respective methyl esters represent the main reaction products. At *p*H higher than 7·0, *S*-ethoxycarbonylcysteine isomerizes readily to *N*-ethoxycarbonylcysteine, and a free thiol is restored; the methyl esters also hydrolyse rapidly. This instability of the primary reaction products to slight shifts of *p*H is probably due to neighbouring groups. In cysteine, the thio-, the amino-, and the carboxy-groups are in close proximity. If the reaction *in vitro* occurs in the presence in the solution of nucleic acids, the latter become methylated mainly at the position 7 of guanine.

As the reaction between MNU and thio-compounds does not require enzymes and proceeds at the physiological range of *p*H, it is suggested that similar events could occur *in vivo*. Concurrent substitution of several reactive groups could occur, possibly in some structural elements which are brought into close proximity to a thiol-group, in the tri-dimensional framework of the cell. The thiol itself may not retain the substituent; estimation of free sulphydryls would then not detect the fact that these groups were primarily involved in the reaction.

The irreversible consequences and cancer which can follow a single dose of MNU[29] may be related to its ability to interact with specific 'sensitive centres' in the cell, possibly such as the sulphur links, which appear to exist between nucleic acids and some residual proteinaceous material. The well-known difficulties of removal of the residual small amount of proteinaceous materials from

isolated nucleic acids, whether from mammalian tissues or viruses, might indicate a specific biological role of these sites.

PHOTOSENSITIZATION AND LYSOSOMAL DAMAGE

By Dr. T. F. SLATER and Dr. P. A. RILEY

Department of Chemical Pathology and Department of Dermatology, University College Hospital Medical School, London

ONE type of photosensitization results from the accumulation in the blood and tissues of substances normally eliminated in the bile; it is the accumulation of such substances which provokes the characteristic reaction of the skin to light. In several such instances with livestock the major factor in the photosensitization has been demonstrated to be the chlorophyll degradation product, phylloerythrin[1,2]. This porphyrin is but one of many such photosensitizers which have been experimentally shown to lead to abnormal reactions of the skin to light following their parenteral administration (for reviews see Clare[3], Blum[4]). For example, see the early work of Jodlbauer and Busck[5] with fluorescein dyes, and the experiments of Hausmann[6] and of Solomon[7] using haematoporphyrin. The latter experiments are of interest in relation to the well-known photosensitization associated with certain types of porphyria. Many photosensitizers are coloured substances and can exhibit their deleterious action in conjunction with light of the visible region. This is a useful, though not infallible, feature distinguishing porphyria from sunburn, which is commonly taken to be dependent on ultra-violet radiation for its development.

The absorption of light energy by a photosensitizer can be taken to result in the formation of an excited state. In some instances the full development of the photosensitization reactions has been shown to require oxygen[8] and to be essentially independent of temperature[9]. These findings suggest that an essential part of the process (at least in the particular instances investigated) is the formation of oxygen-containing free radicals of the peroxy-type. Such radicals are readily formed by the interaction of molecular oxygen and many other free radical systems[10]. If this view is correct, such an event would be harmful to the cells in which the reaction occurred (for example, epidermal cells). Lipid peroxidation, a process involving such radicals, is known to have a powerfully damaging action on lipid rich structures, for example, the many types of membrane system present in the cells[11]. The intracellular formation of significant quantities of such destructively reactive radicals would result in damage to mitochondria, the endoplasmic reticulum, lysosomes, and the external cell wall itself. The actual extent and intracellular localization of the damage would depend on many factors. For example: (*a*) the site or sites of production of the radical; free radicals are known[12] to have an effective sphere of influence in biological material of about 30 Å; (*b*) the concentration and nature of the radicals produced; and (*c*) the intracellular localization of free radical chain terminators (for example, vitamin E). Tappel and colleagues have clearly shown[13] that free radicals induced by a variety of methods (ultra-violet irradiation; cobalt-60 irradiation; hydrogen peroxide decomposition) caused rupture of a purified preparation of rat liver lysosomes. Swelling of mitochondria was also demonstrated in similar experiments[14], although high concentrations of radicals were required for both these purposes.

The possibility therefore arises that the action of photosensitizers can be placed on a biochemical basis by considering that they function as initiators of free radical (chain) reactions, the free radicals thus produced then causing disruption of intracellular membrane systems with consequent damage to, and eventually even the death of, the cells concerned. In this communication we present evidence for the validity of this argument, based on studies of one type of membrane-limited intracellular particle—the lysosome.

For experiments involving the use of liver homogenates, adult female albino rats were used. They were killed by cervical dislocation and the liver quickly removed, weighed and homogenized in 9 volumes ice-cold 0·25 M sucrose. The homogenate was centrifuged for 10 min at 600*g* to remove nuclei, red cells and debris; the supernatant was then centrifuged for 15 min at 15,000*g* to sediment a large particle fraction. This was re-suspended in ice-cold 0·70 M or 0·25 M sucrose.

Acid phosphatase in this fraction was estimated by the method of Berthet and de Duve[15], incubation time 10 min at 37° C, *p*H 5·0. β-Glucuronidase was estimated as described by Gianetto and de Duve[16]. Acid sulphatase was measured by the method of Roy[17]. Free and total activities of each enzyme were determined in the absence or presence of 'Triton *X*-100' respectively[18].

The effect of phylloerythrin and/or irradiation on the latency[19] of these acid hydrolases was determined in the following manner. A sample of untreated suspension and another containing phylloerythrin were irradiated in a cold-room at 2° C using an ordinary household electric lamp (60 W, distance 15 in.) for 30 min–1 h; stirring was

achieved using a magnetic stirrer. A pair of identical samples was also placed on top of the magnetic stirrer but was completely protected from light by enclosure in a thick cardboard box. In other experiments, irradiation was performed using a mercury vapour lamp under similar conditions.

For experiments involving skin sections, adult female albino rats were killed and the tail skin dissected off and frozen in carboxy-methyl cellulose at −20° C. Cryostat sections 7μ thick were cut and fixed for 10 min in ice-cold buffered formol–calcium (*p*H 7·2) washed in distilled water and treated for 10 min at room temperature with the following reagents: barbitone/HCl buffer (*p*H 7·2), buffered phylloerythrin solutions of differing dilution, buffered hydrocortisone sodium succinate, and buffered *d*-α-tocopheryl polyethylene glycol 1,000 succinate. The sections were irradiated in fluid-filled watch-glasses with light from a mercury vapour lamp (H.B.O. 200) for periods between 10 sec and 30 min, and subsequently washed in distilled water and incubated to demonstrate acid phosphatase activity. This was determined by a variant of Gomori's method[20]; sections were incubated for 1 h at 37° C.

Liver experiments. In this communication only the results found for acid phosphatase activity will be discussed in any detail. Irradiation alone (either visible or ultra-violet) produced a small decrease in the bound/free activity ratio for acid phosphatase (Table 1). This ratio is a measure of the intactness of the lysosomal membrane. Phylloerythrin alone produced a small rise in the bound/free activity ratio; the total activity was not significantly altered. However, the application of irradiation (either ultra-violet or visible) to the suspension containing phylloerythrin produced a considerable decrease in the bound/free activity ratio and in this case the total activity was also sometimes decreased. Thus, so far as acid phosphatase is concerned, phylloerythrin stimulated an irradiation-induced rupture of the large particles.

Table 1

Treatment	Phylloerythrin concn. (μM)	Total activity (% control)	Bound/Free Activity
(*a*) —	—	100	1·89
Irradiated	—	122	1·62
Phylloerythrin	100	116	2·25
Phylloerythrin + irradiation	100	130	1·42
(*b*) —	—	100	1·72
Phylloerythrin	60	94	2·50
Phylloerythrin + irradiation	60	77	1·44
(*c*) —	—	100	3·97
Irradiation	—	96	3·40
Phylloerythrin	70	98	4·80
Phylloerythrin + irradiation	70	84	3·10

Effect of phylloerythrin and of irradiation (60 min at +2° C) on rat liver acid phosphatase activity in large-particle suspensions prepared by differential centrifuging of sucrose homogenates. Three typical experiments are shown involving (*a*) and (*b*), ultra-violet irradiation of particles suspended in 0·7 M sucrose; (*c*) visible light irradiation of particles suspended in 0·25 M sucrose. Total enzyme activity was measured after bursting lysosomes with 0·1 per cent 'Triton-*X*-100' and values are expressed as a percentage of the control value. The bound/free activity ratio reflects the integrity of the lysosomal membrane at the end of the treatment period. Other details are in the text.

This pattern was not constant with the other enzymes studied. For example, irradiation of phylloerythrin-containing samples did not decrease the total β-glucuronidase activity and similar treatment did not cause significant alteration in the bound/free activity ratio of acid sulphatase.

Skin experiments. Buffer-treated sections showed no significant loss of punctate acid phosphatase activity until they had been irradiated for between 20 and 30 min (Fig. 1). Unirradiated sections treated with phylloerythrin showed marked punctate staining in the epidermis, indistinguishable from controls. Punctate staining was completely abolished in sections treated with phylloerythrin (final concentration 78–390 μM) and subsequently irradiated in buffer for 10 sec. A clear reduction in punctate staining was obtained in sections treated with very high dilutions of phylloerythrin (final concentration 7·8 mμM) and irradiated for 10 sec as compared with buffer-treated controls. Sections pre-incubated in phylloerythrin (390 μM) and placed in hydrocortisone before irradiation (10 sec) retained this punctate staining. Sections pre-incubated in phylloerythrin (78 μM) and placed in *d*-α-tocopheryl polyethylene glycol 1,000 succinate before 10-sec irradiation retained some particulate activity which was greatest in those treated with a dilute solution of the protector (0·005 mg/ml.) rather than a strong solution (0·5 mg/ml.).

The results outlined here show that phylloerythrin greatly potentiates the irradiation-induced rupture of particles rich in acid phosphatase activity in rat liver and rat tail epidermis. In this respect phylloerythrin is effective at a low final concentration and can utilize light energy of the visible region.

It is clear, however, that the effect of phylloerythrin on liver lysosomes is less marked than that on acid phosphatase-containing particles in rat tail epidermis. Liver lysosomes seem in this relative sense to be comparatively stable, a finding consistent with earlier results that high doses of free radicals were necessary for their rupture[13]. Liver lysosomes are also little affected during the early stages of acute liver injury[21] whereas they are rapidly affected by ischaemic anoxia[22].

It is our experience in using histochemical methods to demonstrate lysosomal particles that widely differing

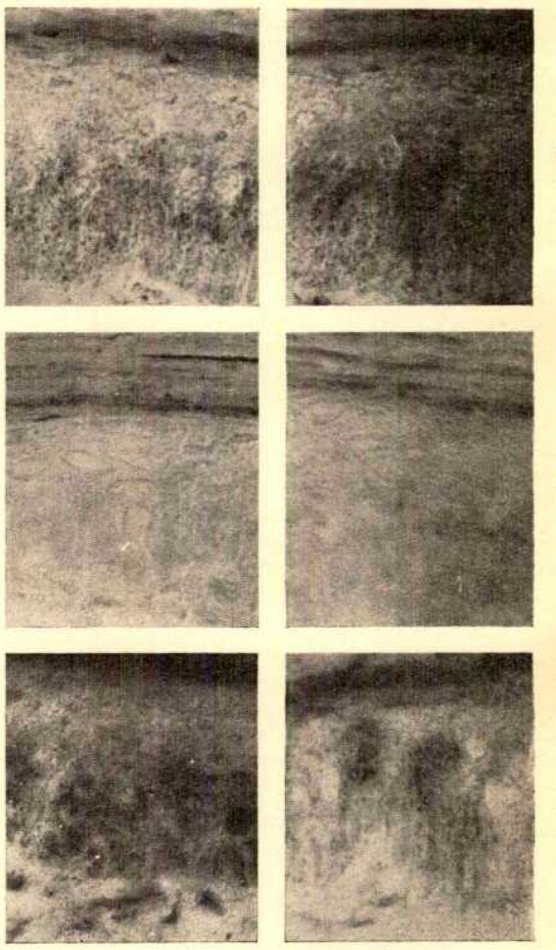

Fig. 1. Lysosomal acid phosphatase activity in rat tail epidermis. (*a*) Section treated with phylloerythrin (78 μM) but not irradiated prior to incubation. (*b*) Untreated control. (*c*) Section treated with phylloerythrin (78 μM) and irradiated for 10 sec prior to incubation. (*d*) Section treated with phylloerythrin (7·8 mμM) and irradiated for 10 sec prior to incubation. (*e*) Section treated with phylloerythrin (390 μM) and protected by hydrocortisone (1 per cent) during irradiation (10 sec). (*f*) Section treated with phylloerythrin (78 μM) and protected by tocopherol (0·0005 per cent) during irradiation (10 sec)

fragilities of these organelles occur in different tissues which demand appropriate adaptations in technique. These different fragilities may represent variations in reaction to the adverse conditions present during incubation as well as possible differences in the lysosomal structures themselves. Species differences also exist; for example, in human and in mouse tail epidermis in which lysosomal acid phosphatase activity has been demonstrated, the incubation times giving optimum punctate staining are 40 min and 75 min respectively. Rat tail epidermis gives good results after 60 min incubation, and by virtue of the relative simplicity of the technique and the ease with which effects on lysosomal staining can be produced, and observed, this material would appear advantageous as a useful tissue for an *in vitro* screening test for potential photosensitizers and protectors.

We have little direct evidence as to the detailed mechanism by which phylloerythrin induces lysosomal rupture on irradiation. However, the demonstration by Magnus, Porter and Rimington[23] that the action spectrum for the oedematous component in the photosensitization produced by porphyrins coincided closely with the positions of their Soret bands leaves little doubt that it is an excited form of the photosensitizer which is effective in this respect (that is, the Grotthuss–Draper law applies to these systems). It is possible that a free radical form of the photosensitizer is a consequence of this excitation stage. Mauzerall and Feher[24] have demonstrated the existence of porphyrin free radicals; a further example for this suggestion is the related pentaphenyl-pyrrolium ion radical which is stable[25]. (A short discussion on the occurrence of triplet states in porphyrin molecules following excitation is given by Reid[26].) Of more direct relevance, Norins[27] has shown a measurable increase in free radicals in skin following ultra-violet irradiation. The formation of significant intracellular quantities of extraneous free radicals can be expected to be injurious to the cells concerned. In particular, in the presence of oxygen, radicals of the peroxy type can be expected to be produced. In the presence of lipid-rich membranes such a production of peroxy-radicals would lead to the formation of lipid peroxides with consequent disorganization of the specific structural features of these membrane systems. Lipid peroxidation has been implicated in previous reports dealing with various types of cell damage[11].

The dependence of photosensitization on the level of oxygen[8] and the virtual independence of the disturbance to temperature variation[9] suggests a similarity to numerous examples of photodynamic action previously reported. In the latter events, the reactive species appears to be a triplet state (that is, a free radical structure)[28] of the sensitizer molecule which subsequently interacts with oxygen. It is interesting to note that powerful photodynamic effects in a series of dyes have been correlated with their fluorescence[26], and that an approximate correlation between photodynamic action and carcinogenicity has been reported by Alexander[28].

In view of the foregoing speculative remarks concerning the role of free radicals in phylloerythrin-induced photosensitization, we tested two substances which can function as chain terminators: vitamin E (as the soluble succinate salt) and hydrocortisone. Vitamin E is a well-known antioxidant and also inhibits reactions proceeding by way of a radical step[29]. Hydrocortisone has been shown to stabilize lysosomal preparations *in vitro* against various types of damage including irradiation[30]. Both vitamin E and hydrocortisone protected skin lysosomes against the combined influence of phylloerythrin and irradiation. These findings are consistent with the hypothesis suggested here.

However, despite the demonstration that low concentrations of phylloerythrin can enhance lysosomal lysis following irradiation, this certainly cannot be taken to imply that such a reaction is the sole and/or major cause of epidermal cell injury in cases of photosensitization induced by phylloerythrin. Other types of intracellular structure, for example mitochondria and endoplasmic reticulum, are known to be damaged by free radical-producing reactions. It is quite probable also that the cell membrane itself would suffer damage in the course of such reactions. If the energy system maintaining the sodium pump[31] were affected, then an increased water content of the cells would follow. A further intracellular organelle likely to suffer damage by lipid peroxidation and/or free radical interaction is the mast cell granule[32]. This could be of relevance to the erythematous component of the photosensitization. On the other hand, lysosomes possess properties which make them unique candidates for increasing the range and extent of cell damage resulting from absorbed radiation. By such a free-radical mechanism it is possible to conceive how irradiation of a small area of cytoplasm can cause a wide area of damage throughout the cell. In this connexion the speculations raised here come very close to the conclusions of Bacq and Alexander[33] on the mechanism of cell necrosis following irradiation. These authors proposed that the primary lesion was an alteration in membrane permeability resulting in the release of catabolic enzymes.

The mechanism proposed here for lysosomal rupture based on a free radical reaction does not necessarily entail uptake of the photosensitizer by the lysosome. Formation of significant numbers of radicals in the immediate neighbourhood of lysosomes should be quite sufficient for the production of lysis. However, adsorption of the reactive species (for example, phylloerythrin) in the lysosomal membrane prior to excitation would presumably be even more effective. The uptake of dyes and fluorescent materials by lysosomes from various tissues (for example, liver, kidney, HeLa cells) has been studied by many investigators[34]. It is possible that this uptake is primarily a reflexion of the pinocytotic activities of the cells concerned. If so, then considerable variations must be expected from tissue to tissue in this respect and, for instance, autofluorescence of epidermal lysosomes has never been observed by us even in sections from rats with ligated bile ducts, dosed systemically 24 h previously with phylloerythrin.

Finally, we think it worth speculating on the implications of such an uptake in terms of a physiological lysosomal function. Lipofuchsin accumulation is thought to represent an end product of one form of lysosomal deterioration[35]; the pigment is believed to arise from peroxidation of various types of intracellular lipid engulfed by the original lysosome[36]. If true, this process would be an example of a naturally occurring lipid peroxidation taking place within the lysosome. It is possible that the sequestration of toxic fluorescent material by lysosomes[37] in several tissues represents a defence mechanism rather than primarily an injurious event. That is, an attempt to remove potential chain initiators from the oxygen-rich cytoplasm, where peroxidation of sensitive lipoprotein membranes would seriously endanger the cell, into the lysosomes where peroxidation could be diverted into a process akin to lipofuchsin formation. Failure of such an uptake, leading to the initiation of cytoplasmic peroxidative chain reactions and wholesale rupture of lysosomes as shown here, could account for the isolated necrosis observed with such fluorescent materials, as has been pointed out recently[37].

A physiological process which, perhaps, provides an example of the speculation raised here is the enveloping of melanin granules by phospholipid membranes[38]. The protective function of melanin, involving absorption of radiant energy, is considered to involve free radical formation[39] which, on the basis of work presented here, would be potentially damaging to the epidermal cells unless confined and dissipated in a controlled manner.

One of us (P. A. R.) acknowledges the tenure of a Medical Research Council Research Fellowship. We are

grateful to Prof. C. Rimington for many helpful comments and for stimulating and initiating our interest in this problem.

METABOLISM OF AFLATOXIN IN SHEEP: EXCRETION OF THE 'MILK TOXIN'

By Dr. R. ALLCROFT, O.B.E., H. ROGERS and G. LEWIS
Central Veterinary Laboratory, Weybridge, Surrey
AND
Dr. J. NABNEY and P. E. BEST
Tropical Products Institute, 56–62 Gray's Inn Road, London, W.C.1

COWS fed groundnut meal containing aflatoxin B_1 excrete in their milk a toxic factor which causes liver changes in ducklings indistinguishable from those produced by aflatoxin[1]. de Iongh *et al.*[2] showed that the toxicity of this milk was determined by the presence of a blue-violet (BV) fluorescent component, called the 'milk toxin', which had an R_F value well below that of pure aflatoxin B_1. They also demonstrated that the lactating rat was able to convert aflatoxin B_1 into this 'milk toxin'. Butler and Clifford[3] have shown the presence of this component as well as aflatoxin B_1 in the livers of rats given pure aflatoxin B_1 either orally or intraperitoneally, indicating that at least some aflatoxin B_1 is converted in the liver to the 'milk toxin'.

Sheep appear to be resistant to aflatoxin[4]. This is a peculiarity not shared by other species so far tested. In view of this resistance, the occurrence of aflatoxin or its metabolites in tissues and urine of sheep given a single dose was investigated.

Three yearling sheep were each given a dose (1 mg/kg) of mixed aflatoxins (B_1 36 per cent; G_1 52 per cent; B_2 3 per cent; G_2 2 per cent) dissolved in 2 ml. dimethylformamide, two by stomach tube and one by intraperitoneal injection. All were killed 2 h later; liver and kidney were removed and portions extracted for examination by thin-layer chromatography by the method described by de Iongh *et al.*[5], using 2 per cent methanol in chloroform as developing solvent. Urine samples were taken before dosing, 1 h after, and at death; a 60 per cent methanol–urine mixture was repeatedly extracted with chloroform and these extracts were concentrated and spotted on to chromatoplates similar to those used for the tissue extracts.

Fig. 1 shows the fluorescent spots seen when viewed in ultra-violet light. The liver extracts of all sheep showed the BV and blue-green (BG) spots at R_F values corresponding to the standard mixed aflatoxins B_1 and G_1 and also a slow running BV spot at R_F 0·2, the 'milk toxin' spot (M_2). This was less intense than the B_1 and G_1 spots. The kidney extracts showed fluorescent spots similar to those seen in the liver extracts, but the intensity of the 'milk toxin' spot at R_F 0·2 was much greater, whereas the B_1 and G_1 spots were less intense.

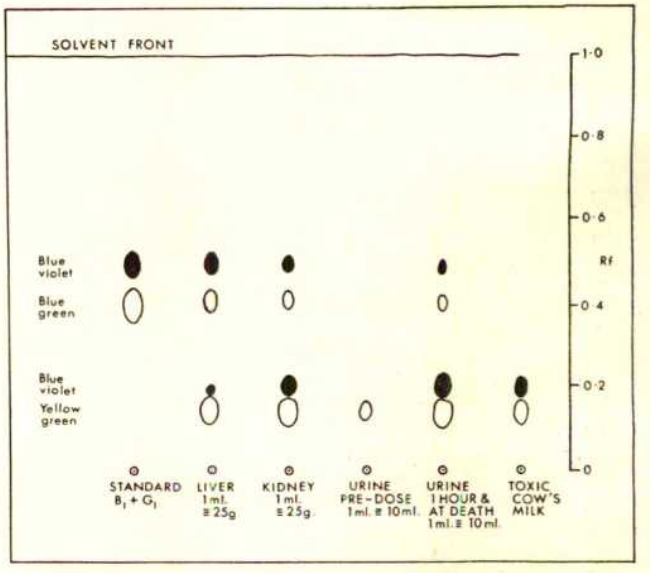

Fig. 1. Thin-layer chromatography of extracts of mixed aflatoxins B_1 and G_1; liver and kidney of sheep dosed with aflatoxins B_1 and G_1; urine from sheep before and after dosing; toxic cows' milk

The urine samples taken from the sheep before dosing showed no fluorescent spots except a yellow one at R_F 0·1 (U_3) which appears to be present in extracts of all tissues. The urine samples taken 1 h after dosing and from the bladder at death showed very intense *BV* 'milk toxin' spots (M_2), faint B_1 spots and somewhat stronger G_1 spots.

The R_F of the 'milk toxin' spot varied with the polarity of the solvent and the activity of the plate, so that a reference spot of authentic 'milk toxin' should be run on the plate if possible.

Although the findings reported by Butler and Clifford[3] indicated that the toxic component in milk was comparable to the slow-running *BV* spot obtained in extracts of rat liver and blood, it seemed desirable to investigate the identity of these compounds more rigorously. Since the amount of this component present in the urine of sheep dosed with aflatoxin was greater and more easily extracted than that present in the liver, it was decided to purify and compare the milk and urine components.

Several 500-g portions of dried toxic cows' milk were extracted for 6 h with light petroleum (40–60° C) in a Soxhlet extractor, air dried and re-extracted with methanol for 6 h. (Further extraction with methanol or chloroform yielded no more milk toxin.) The toxic fraction of this extract was concentrated as described by de Iongh *et al.*[2].

The combined residues from several extractions were then fractionated on a column of silica gel (20 g per 500 g of dried milk). The column was observed in ultra-violet light, a weak blue fluorescent band was eluted by chloroform (M_1), and a stronger *BV* fluorescent band by chloroform containing 2 per cent methanol (M_2, the milk toxin).

Further purification of M_1 and M_2 was achieved by repeated thin-layer chromatography on 'Kieselgel *G*' chromatoplates (thickness 750μ), portions of solutions of the column fractions being applied in a line across the bottom of the plate and using chloroform containing 3 per cent methanol as developing solvent. The fluorescent bands observed when the plate was viewed in ultra-violet light were similar in pattern to the spots described by de Iongh[2]. In each case the silica gel containing the blue fluorescent band was scraped from the chromatoplate, and eluted with cold methanol. The residue from the evaporation of the methanol filtrate was rechromatographed; this process was repeated until the material gave a single, well-defined spot on thin-layer chromatography.

The chloroform extract of urine from one of the sheep which had been dosed with mixed aflatoxins was also subjected to similar treatment. The plates showed three main fluorescent bands, *BG* (U_1), *BV* (U_2) and yellow (U_3) at R_F 0·45, 0·4 and 0·35, respectively. Purification by thin-layer chromatography was carried out as already described here.

These purified materials were then investigated chromatographically and spectroscopically.

The very small amount of M_1 had the same R_F as aflatoxin B_1, and thin-layer chromatography of a mixture of these two, using chloroform containing 2 per cent methanol for development, yielded only a single spot. It would appear probable that M_1 is aflatoxin B_1. Similarly, a mixture of U_1 and aflatoxin G_1 showed only a single spot and it is likely that these two compounds are identical.

Both M_2 and U_2 showed a long wave-length absorption maximum at 355 mμ in the ultra-violet, and the fluorescence spectra of both showed an emission peak at 425 mμ when excited at the maximum of 355 mμ. A mixture of M_2 and U_2 was subjected to thin-layer chromatography as shown in Table 1.

Table 1

Developing solvent	R_F	No. of spots
Trichloroethylene, chloroform, methanol (8 : 1 : 1)	0·25	1
Chloroform, methanol (97 : 3)	0·4	1
Ethyl acetate, methanol (9 : 1)	0·5	1
Trichloroethylene, acetone (1 : 9)	0·8	1

It would appear very probable that M_2 and U_2 are identical. The close resemblance of the spectral data of this substance to that of the aflatoxins[6] would make it appear possible that the main chromophoric system is similar.

If it is assumed that the extinction coefficient of the peak at 356 mμ in the 'milk toxin' is similar to that at 363 mμ in B_1, and that the molecular weights of the two compounds are also similar, then the amount of toxin present can be estimated spectrophotometrically as described previously for aflatoxin B_1 (ref. 7). (The ε values of the 363 mμ peak of the four aflatoxins are all about 20,000 (ref. 6).) On this basis the dried toxic cows' milk investigated averaged 10 μg toxin/kg.

Samples of urine can usually be obtained easily, and since extraction of up to 120 ml. of urine can be completed in about 6 h and the concentrate, without further treatment, can be spotted and run on a thin-layer chromatoplate, the presence of aflatoxin or 'milk toxin' spots on this may provide a useful field test for checking the ingestion by man or animals of aflatoxin-containing foods in those countries where *A. flavus* is ubiquitous.

Since the compound now referred to as the 'milk toxin' appears to be present in the liver, kidney and urine as well as in the milk of animals ingesting aflatoxin, it would seem no longer useful to retain the name 'milk toxin', and we suggest giving this compound the trivial name 'aflatoxin *M*', which indicates the original derivation from milk but is of more general applicability.

MOLECULAR WEIGHTS OF PROLACTINS AND PITUITARY GROWTH HORMONES ESTIMATED BY GEL FILTRATION

By Dr. P. ANDREWS

National Institute for Research in Dairying, Shinfield, Reading, Berkshire

PRESENT knowledge of the molecular weights of prolactins and growth hormones is based largely on ultracentrifuge data, but reversible and irreversible aggregation of the hormones has sometimes rendered measurement difficult[1]. The fact that most of the reported molecular weights of growth hormones[2–7] were determined at about *p*H 2·3 or *p*H 10 also raises some doubt as to their molecular weights at physiological *p*H. As preliminary gel filtration experiments[8] indicated that the molecular weights of ox, pig and sheep growth hormones at *p*H 7·5 are considerably less than the presently accepted values, the subject has been investigated further. As a background to the use of gel filtration in this connexion, Andrews[9,10] has shown that the gel filtration method

gives useful estimates of the molecular weights of carbohydrate-free globular proteins over a wide range of molecular weights. In addition, the method seems to have special application to the estimation of the monomer molecular weights of proteins which show concentration-dependent association–dissociation behaviour[9–12].

Sheep prolactin (lots No. NIH-*P-S3* and *-P-S4*) and human (NIH-*GH-HS*269), monkey (NIH-*GH-M*655*A*), ox (NIH-*GH-B*2, *-GH-B*4 and *-GH-B*5), pig (NIH-*GH-P*476*C*) and sheep (NIH-*GH-S*646*A*) growth hormones were kindly provided by Dr. A. E. Wilhelmi and the Endocrinology Study Section, U.S. National Institutes of Health, ox prolactin by Dr. K. A. Ferguson, and human growth hormone, prepared by the Raben method[13], by Drs. A. Korner and M. S. Raben. A sample of human growth hormone monomer purified by gel filtration (Forsyth, Isabel A., and Andrews, P., unpublished work) was also used.

'Sephadex *G*-100' gel filtration columns (50 cm × 2·4 cm diam.) were used for molecular weight estimation as described by Andrews[9]. The columns were equilibrated with 0·05 M H_3PO_4 containing 0·1 M KCl and sufficient NaOH to bring the *p*H to 1·9, 2·5, 3·2, 4·0, 5·0 or 6·2, with 0·05 M *tris*-HCl (*p*H 7·5) plus 0·1 M KCl, or with 0·05 M H_3BO_3 containing 0·1 M KCl and sufficient NaOH to bring the *p*H to 8·5, 9·5, 9·9 or 10·3. Although the equilibration solutions had little or no buffering action at some *p*H's, no deviation from the required *p*H during column runs was detected. All experiments were performed at 2–5° C.

The columns were calibrated for molecular weight estimation at *p*H 7·5 and higher *p*H's with cytochrome *c*, ribonuclease, α-lactalbumin, myoglobin, soya bean trypsin inhibitor, ovalbumin and bovine serum albumin (see Andrews[9]). Calibration at *p*H's below 7·5 was based on ribonuclease, α-lactalbumin, ovalbumin and bovine serum albumin, which showed similar behaviour relative to each other over the whole *p*H-range investigated.

Samples were generally dissolved in 2 ml. of the equilibration solution for application to the columns, but at some *p*H's dissolution of the hormones was difficult. In such cases they were first dissolved in 0·2 ml. of 0·02 N NaOH, 1·6 ml. of equilibration solution was added, and the *p*H was adjusted with 0·02 N HCl. Serum albumin, ovalbumin or cytochrome *c* was included in each column run as a standard, the choice depending on the gel filtration behaviour of the hormone. Column effluents were collected in 3 ml. fractions, and protein concentration in the effluents was determined by extinction at 210, 215, 230, 280 or 410 mμ, depending on the nature and quantity of protein involved.

Sheep and ox prolactins. Elution diagrams (cf. ref. 14) indicated the presence of monomer (72 per cent and 82 per cent of the total protein, based on extinction measurements, in NIH-*P-S3* and *-P-S4*, respectively) and aggregated material in both sheep prolactin preparations. Estimations on 3 mg of either preparation indicated a monomer molecular weight of 23,500–24,000 at *p*H 7·5, but experiments with smaller amounts showed a concentration-dependent association of the monomer (Fig. 1*a*). Extrapolation to infinite dilution gave 20,000 as the monomer molecular weight. Greater aggregation of the monomer occurred in the range of *p*H 2–5 (Fig. 1*b*), but the very low solubility of the hormone in this region precluded further investigation.

Molecular weight estimates of 20,900 and 22,400 on 0·3 mg and 1·3 mg samples, respectively, of ox prolactin at *p*H 7·5 indicated a monomer molecular weight at infinite dilution of 20,500. An estimation at *p*H 2·5 (31,200) showed aggregation at low *p*H similar to that of sheep prolactin.

Human growth hormone. Elution diagrams indicated that the human growth hormone samples prepared by the Raben method contained only ~ 60 per cent monomer compared with 80 per cent in the NIH preparation and > 95 per cent in the monomer preparation. In every case, however, monomer molecular weights estimated at *p*H 7·5 were 21,000–22,500 when portions containing 0·5 mg of monomer were used, and further measurements extrapolated to infinite dilution (Fig. 1*c*) gave 20,500. Slight aggregation at higher and lower *p*H's was detected (Fig. 1*d*). The Raben preparations appeared to contain at least 20 per cent of dimer (mol. wt. 44,700).

Monkey growth hormone. The main component, presumably monomer (70 per cent of the total protein), of a 0·8 mg sample had a molecular weight of 21,000 at *p*H 7·5.

Ox, pig and sheep growth hormones. All the preparations contained 75 per cent or more of monomer. Molecular weights estimated on 1·0–1·2 mg samples at *p*H 7·5 were in the range 27,000–30,000, but allowance for concentration-dependent association (Fig. 1,*e,g*) indicated monomer molecular weights of 26,000, 22,500 and 24,000 for the ox, pig and sheep hormones, respectively. Aggregation of the ox hormone increased markedly at low *p*H, reaching a maximum at about *p*H 2·3 with a molecular weight indicative of dimer formation, but increased aggregation in alkaline solution was not observed (Fig. 1*f*). Experiments with 8 mg and 23 mg samples of ox growth hormone showed some concentration-dependence in its gel filtration behaviour at *p*H 10·3. Aggregation of the pig and sheep hormones also increased at low *p*H, since their molecular weights estimated at *p*H 2·5 (1 mg samples) were 36,700 and 39,000, respectively, but values at *p*H 9·5 and 10·3 were similar to those at *p*H 7·5.

Effect of storage on hormones in solution. All the foregoing molecular weight estimations were performed on freshly prepared solutions. To check for hormone degradation[15–17] during the time required for column runs (6–12 h), measurements at *p*H 7·5 were repeated on hormone solutions which had been stored at these *p*H's for at least 24 h in the cold. The estimated molecular weight of one ox growth hormone preparation (NIH-*GH-B*2) decreased by 20 per cent after storage for 24 h, but thereafter it remained constant. Otherwise no significant changes were detected.

The good agreement between molecular weights determined in the ultracentrifuge for sheep prolactin[14,18]

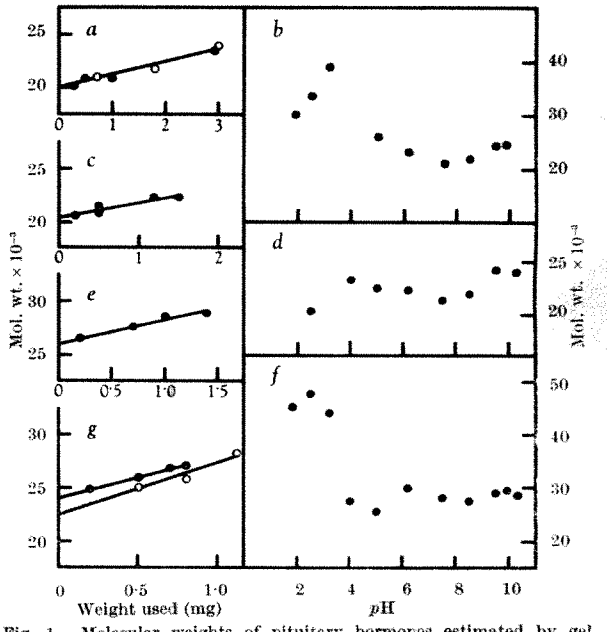

Fig. 1. Molecular weights of pituitary hormones estimated by gel filtration. *a*, Concentration-dependence, and *b*, *p*H-dependence (1-mg samples), for sheep prolactin NIH-*P-S3* (○) and NIH-*P-S4* (●). *c*, Concentration-dependence, and *d*, *p*H-dependence (0·5-mg samples), for human growth hormone NIH-*GH-HS*269. *e*, Concentration-dependence, and *f*, *p*H-dependence (1·2-mg samples), for ox growth hormone NIH-*GH-B*4. *g*, Concentration-dependence for pig growth hormone NIH-*GH-P*476*C* (○) and sheep growth hormone NIH-*GH-S*646*A* (●)

and human growth hormone[3] monomers and the molecular weights estimated by gel filtration for these hormones indicates that the gel filtration method is applicable to this type of protein. Aggregation of sheep prolactin in acid solution is evident both in the ultracentrifuge[14] and from its gel filtration behaviour (Fig. 1*b*). Sheep and ox prolactins appear to have about the same molecular weight and for ox prolactin the value is somewhat lower than the one originally proposed[19].

The gel filtration results clearly favour 21,500 (ref. 3) rather than 29,000 (ref. 1) as the molecular weight of human growth hormone, and they indicate that human and monkey growth hormones are very similar in size. On this account, a revision of the value of 25,400 for the monkey hormone[4] may be required. The higher literature value[1] for the molecular weight of human growth hormone presumably resulted from the presence of dimer and other aggregated material in the sample used for measurement, since the lower value[3] was determined on the purified monomer. The same reason may in part account for the differences between molecular weights determined in the ultracentrifuge at *p*H 9·9 for ox[5] (45,000), pig[3] (41,600) and sheep[7] (47,400) growth hormones and those estimated by gel filtration, for the latter method reveals no marked aggregation of these hormones at high *p*H. On the other hand, aggregation of ox growth hormone equivalent approximately to dimer formation at *p*H 2·3 is indicated by gel filtration, so that at this *p*H the ultracentrifuge[5] and gel filtration results are in agreement. Pig and sheep growth hormones also appear to aggregate at low *p*H. However, the molecular weight of 25,000 for pig growth hormone given by Wilhelmi[20] does accord with its gel filtration behaviour at physiological *p*H.

Except in one case, storage of the hormones in solution resulted in no change in their gel filtration behaviour, indicating that the low molecular weights estimated by gel filtration are not a result of hormone degradation[15–17] during the experiments. The exceptional case was the ox growth hormone preparation for which earlier gel filtration experiments[8] gave a molecular weight of 20,000. Whatever its significance, this change in gel filtration behaviour accounts for the differences between the earlier and the present (26,000) estimations of ox growth hormone molecular weight. In the circumstances, the latter value is the preferred one.

The gel filtration results suggest that the pituitary growth hormones of various species are much more alike in molecular weight than is at present believed[2], and moreover that they are similar to the prolactins in molecular weight. One consequence of the indicated uniformity in growth hormone size is that the tentative structure of ox growth hormone proposed by Li[19] needs revision. The similarity between the growth hormones and prolactins is of particular interest in view of the possibility that human growth hormone and human prolactin are identical[21].

I thank Prof. S. J. Folley and Dr. A. E. Wilhelmi for their advice.

DIFFERENCES IN PATTERNS OF AGGREGATION OF MALIGNANT AND NON-MALIGNANT MAMMALIAN CELLS

By Prof. B. HALPERN, B. PEJSACHOWICZ, H. L. FEBVRE and G. BARSKI

Chaire de Médecine Expérimentale du Collège de France, Paris; Service de Cytobiologie de l'Institut de Recherches sur le Cancer; Laboratoire de Culture des Tissus et de Virologie, Institut Gustave Roussy, Villejuif

THE propensity of dissociated cells from a variety of embryonic avian and mammalian tissues to aggregate and to form organized multicellular 'aggregens' has been recently described[1–3].

This article reports the fact that definite differences have been observed in aggregation patterns between malignant and non-malignant cells. Emphasis is placed on the fact that the comparison was carried out on cells derived from the same primitive strains and cultured under identical conditions[4].

Two different strains of cells have so far been examined in this respect: (1) The cell line isolated by Rothschild and Febvre[5] from a Wistar rat embryo and cultured since 1963. These cells are devoid of malignancy when re-inoculated into the rat; they are designated here as the ER_1 line. However, when cultured in certain conditions[4], in the presence of Rous sarcoma virus (Bryan strain), these cells acquire highly malignant potentialities for the homologous animal species. The high cancer cell line is referred to here as CT_4. (2) The cell strains isolated by Sanford *et al.*[6] from a C_3H mouse embryo in 1954. Three different clones originating from the primitive line have been compared from the point of view of their aggregation patterns.

The clone N_2 is devoid of malignant potentialities. None of the 35 C_3H mice inoculated with 2 million cells developed tumours. The modal chromosome number of this line of cells is 62 (ref. 7). The clone N_1, another permanent clone derived from the primitive strain, became spontaneously highly malignant. All animals inoculated with 1 million cells died in less than 50 days, and autopsy showed rapidly growing tumours. The modal chromosome number is 55–56, all being telocentric. (In a recent communication, Scaletta and Ephrussi[8] give for the same strain a modal chromosome number of 49 and a variation range of 46–51.)

Clone M_6 results from hybridation of the two preceding strains. It has been shown that the modal chromosome number of the hybrid cells is of 100–115, and that the clone contains the karyotypes of both 'parental' cells. All lines of the hybrid cells were highly malignant when inoculated into C_3H mice[6]. Fig. 1 shows the morphological aspect of the three cell clones.

The various cell lines were grown in Petri dishes containing Eagle's medium enriched with amino-acids and vitamins, to which had been added tryptose phosphate (10 parts per 100) and horse decomplemented serum (10 parts per 100). Before use, the cells were treated for

3–5 min with a solution of trypsin 'Difco' (0·05 parts per 100) in Moscona's buffer[2] and centrifuged. They were then placed into Erlenmeyer vials containing 3 ml. of culture medium, the *p*H of which was adjusted to 7·4 in an atmosphere of 95 parts per 100 of oxygen + 5 parts per 100 of carbon dioxide. The stoppered vials were placed on the platform of a stirrer model *G* 76-10-25 (New Brunswick Scientific Co., New Brunswick, New Jersey, U.S.A.) rotating at 60–70 revs./min. The results observed were similar to those for the two strains of cells used here.

The cells originating either from the ER_1 or from the N_2 clones formed minute clumps of a few cells in the culture; these were readily disrupted by tapping (Fig. 2). Moreover, only a small percentage of the cells tended to agglutinate, and the majority of them remained isolated and dispersed in the culture medium for the duration of the culture.

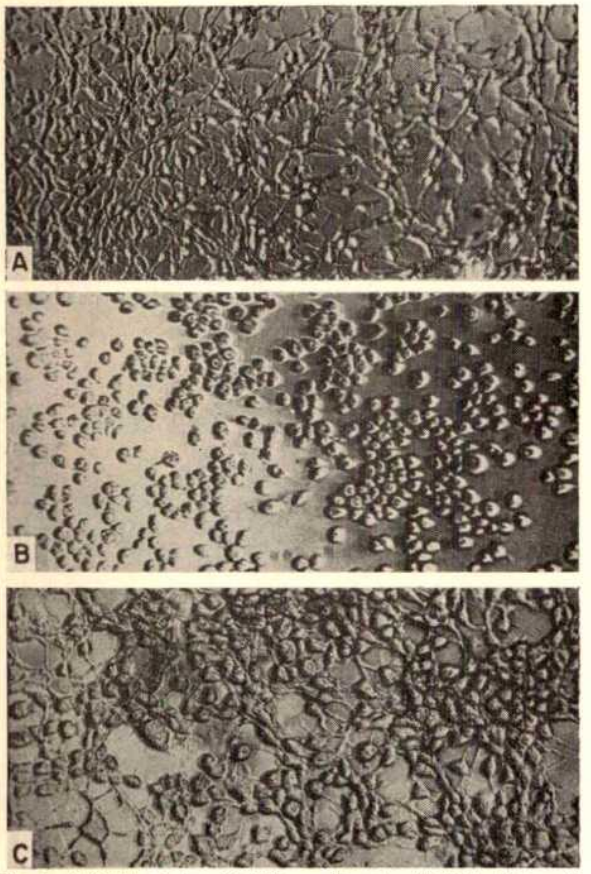

Fig. 1. (*A*) Cells of clone N_1 highly malignant. (*B*) Cells of clone N_2 non-malignant. (*C*) Hybrid cells of the two preceding clones, M_6, highly malignant. (× *c.* 320)

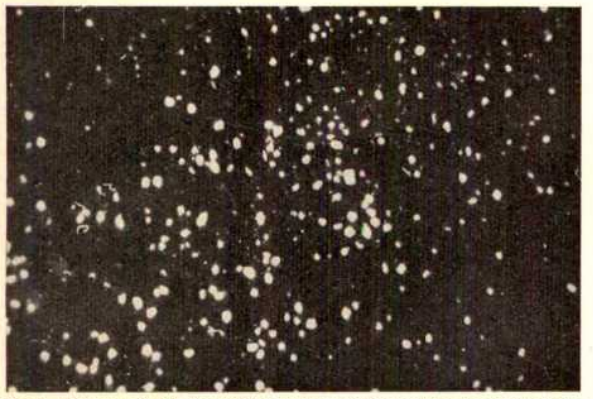

Fig. 2. Clumps of cells formed by the non-malignant N_2 clone cells after 6 days of culture. The majority of the cells are dispersed and isolated. (× *c.* 140)

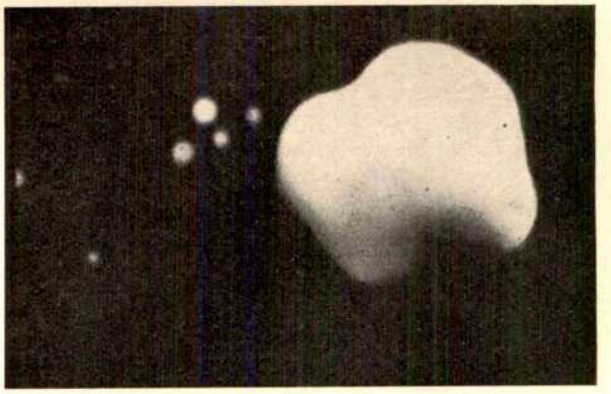

Fig. 3. Aggregates formed by the malignant N_1 clone cells cultured in identical conditions. The size of the *in vitro* formed tumours varies from 0·2 mm to 3 mm and more. The smaller aggregates tend to associate and to develop bigger structures. Fourth day of culture. (× *c.* 8)

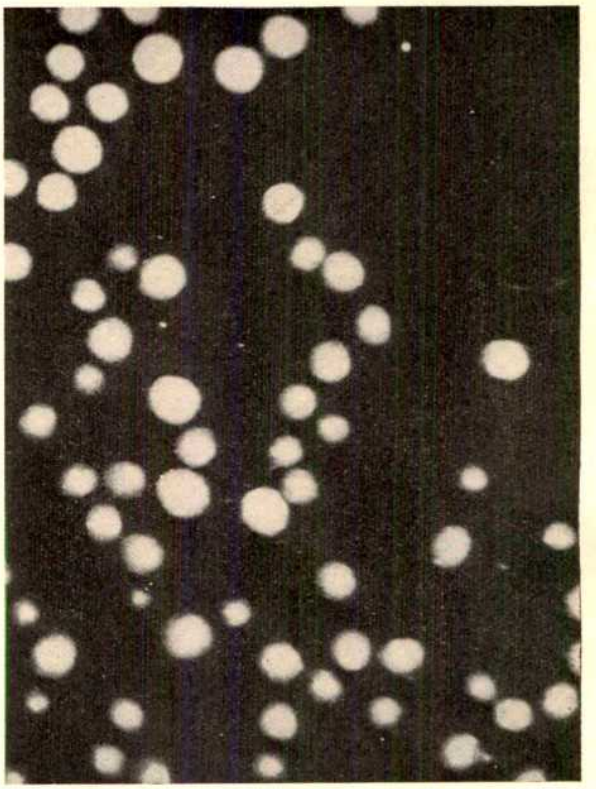

Fig. 4. Aggregates formed by the malignant hybrid M_6 clone cells. Spheroid aggregates of about 0·25 mm diameter. 48 h of culture. No isolated cells in the culture medium. (× *c.* 16)

The behaviour of the malignant cells was quite different. They readily stuck to each other, forming dense aggregates which rapidly increased in size by cell multiplication, and also by the adhering of smaller aggregates to their surface.

In the case of the N_1 clone, the aggregates formed roughly spherical or ovoid structures of 0·5–3 mm diameter within 3–5 days (Fig. 3). Practically no isolated cells were present in the medium. The aggregates were compact, cohesive and showed no tendency to dissociate even when vigorously tapped.

Although the same general patterns of aggregation were observed with all the malignant clones investigated, there seemed to be slight differences in the form and the size of the 'aggregens', depending on the cell strains and the age of the culture. The cells derived from clone CT_4 and from the hybrid M_6 clone formed smaller and roughly spherical aggregates of 0·2–0·4 mm diameter (Fig. 4).

Differences were also observed in the patterns of the migration of the cells from the culture-formed aggregates

Fig. 5. Stationary culture obtained from the clumps of N_2 cells. The cells tend to spread as a monocellular layer. (× *c.* 80)

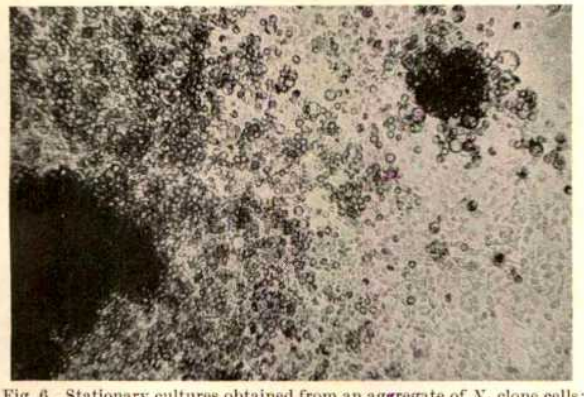

Fig. 6. Stationary cultures obtained from an aggregate of N_1 clone cells: the central part remains compact. The migrating cells tend to form satellite aggregates. (× *c.* 80)

when they were later grown in stationary cultures. The non-malignant cells rapidly spread over the medium and tended to form a regular monocellular layer, reproducing the aspect of the original culture (Fig. 5).

In contrast, the aggregates formed by malignant cells remained compact; the cells migrating from the periphery formed an irregular rim composed mainly of clumped cells which tended to develop satellite aggregates (Fig. 6).

The data reported here provide evidence that a definite difference exists in the aggregation behaviour between malignant and non-malignant cells. The discrepancies were observed with two different strains of cells, and the question arises whether the phenomenon is of a general nature. The non-malignant cells showed no tendency to aggregate when grown in agitated culture. In contrast, the cancerous cells rapidly developed voluminous multicellular tumours. The tumours were formed of cells which had developed an ability to adhere to one another, and which continued to multiply at least as long as the cells could receive nourishment. The cellular cohesion of these tumoral aggregates was strong. Their dimension and their shape depended on the type of cells and on the age of the culture.

In our experimental conditions, the highly malignant N_1 clone cells formed aggregates which were fairly large compared with those formed by the cells originating from M_6 hybrid clones, although the malignancy of both is of the same order. Rat cells rendered malignant by the Rous sarcoma virus behaved like the M_6 clone cells.

The main interest of our observation is in the fact that in both groups of experiments, the comparison was made between malignant and non-malignant cells originating from the same stem strain. The age and the rhythm of multiplication of the malignant and non-malignant clones were as identical as possible. Such a comparative investigation has not, to our knowledge, been carried out before.

In the Sanford strain the malignant clone appeared spontaneously and no explanation is yet available for this mutation, although the possibility of an accidental contamination by viruses cannot be excluded.

In the rat strain obtained from Rothschild and Febvre[5] the malignancy was induced by infecting the culture with Rous sarcoma virus. How far is it possible on the basis of the reported data to assert that there exists a definite correlation between the potential of malignancy and the ability of the cells to form aggregates? In the present state of our knowledge, such a hypothesis can only be conjectural. The aggregation phenomenon is likely to be conditioned by membrane changes which may be of a chemical and/or of a physical nature. The investigation at present in progress, using electron microscopy, indicates some puzzling differences in the membrane structures.

Whatever the real mechanism is, the observations reported here indicate that the malignancy of certain strains of cells whether spontaneous or induced result in an alteration of a biological genetically transmitted property, particularized by the aptitude of the cell to form aggregates. If this phenomenon proves to be a general one, its importance does not need emphasis. The research at present under way aims to provide additional data for the significance and the mechanism of the observed phenomenon.

PRESENCE IN COLIC GLANDULAR CELLS OF VARIOUS MAMMALIAN SPECIES OF AN ANTIGEN CROSS-REACTING WITH HUMAN BLOOD GROUP A SUBSTANCE

By A. ZWEIBAUM, P. OUDEA, Prof. B. HALPERN and C. VEYRE

Centre de Recherches Allergiques et Immunologiques de l'Inserm et de l'Association Claude Bernard, Hôpital Broussais, Paris 14

IT has been known for a long time that antigens similar to human blood group A, and sometimes B substances, exist in the upper gastro-intestinal tract of horse, hog and cow[1–8], and more recently of dog[9] and monkey[10]. This type of antigen seems to be absent in erythrocytes. The presence or absence of these tissue antigens may be important in establishing different groups within the same animal species[1].

Very little, if anything, is known about the presence of this type of antigen in the distal part of the bowel. Such information is much needed, considering the recent extension of investigations on the auto-immune origin of ulcerative colitis in man by means of the immunofluorescent method.

The data reported here indicate that an antigen identical or closely similar to the human blood group A

agglutinogen is present in colic glands of several mammalian species. They also suggest that this antigen is of tissue origin and not a bacterial contaminant.

An indirect immunofluorescent technique (Coons's 'sandwich' technique[11]) was used in all the investigations. 250 normal human sera were tested on alcohol-fixed cryostat sections of fresh, rapidly frozen animal colon and rectum. The following animals were investigated: 32 mongrel dogs, 16 rats (Wistar, Fischer and germ-free rats), 6 Macacus rhesus monkeys. Fluorescent rabbit anti-human γ-globulins were prepared by the method of Goldstein *et al.*[12].

The results obtained with rat colons are shown in Table 1. A bright homogeneous fluorescence restricted to the goblet cells, which indicates a positive reaction, was observed with 81 sera. With all other sera no staining was observed except for a very inconstant and moderate staining of the connective tissue and outer rim of glandular cells. Such a pattern could sometimes be obtained with the fluorescent reagent alone and was not considered to be indicative of a positive reaction. All 16 rats and 6 monkeys reacted in the same way with all positive sera. The picture was different in the dogs, and 13 dog colons only, out of the 32 tested, reacted with the same sera as rats and monkeys ('positive dogs') (Figs. 1 and 2). The other 19 dogs were negative with all sera ('negative dogs').

Table 1. Evidence for the Presence in the Rat Colic Glandular Cells of an Antigen related to Human Blood Group Substance by using the Indirect Immunofluorescent Technique

Blood group	No. of human tested sera	No. of positive sera
A	59	0
B	38	15
AB	20	0
O	133	66

Table 2. Correlation between the Anti-A Agglutinin Titre in Various Human Sera and the Positivity of Immunofluorescent Staining of Rat Glandular Cells

Blood group A erythrocytes agglutination titre of blood group O and B tested sera	No. of tested sera (by immunofluorescence)	Positive staining	Negative staining
1/16	13	5	8
1/32	14	9	5
1/64	17	13	4
1/128	11	10	1
1/256	7	7	0

The positive staining of colic mucosa glandular cells of all three species was abolished by previous absorption of sera with a dry tissue powder prepared from 'positive dog' colic mucosa. Staining was not affected by absorption with a similar powder prepared from 'negative dog' colic mucosa. These results seemed to indicate a specific immunological reaction.

The fact that positive staining was also observed with colons from pre-born and germ-free rats rules out the possible implication of a bacterial antigen.

The close immunological similarity of this tissue colic antigen to human blood group A substance is suggested by the restriction of positive results to sera from O and B groups. The incidence of negative staining with some

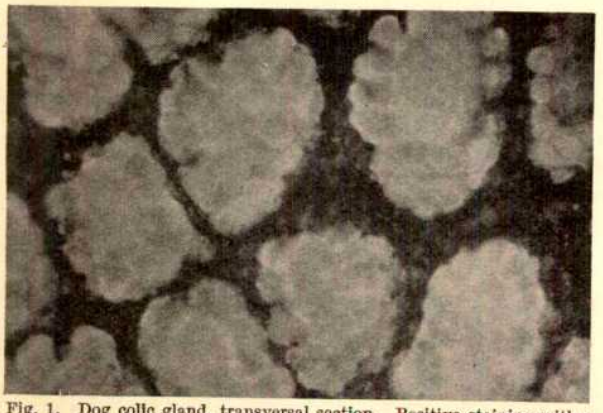

Fig. 1. Dog colic gland, transversal section. Positive staining with a blood group O serum (× *c.* 300)

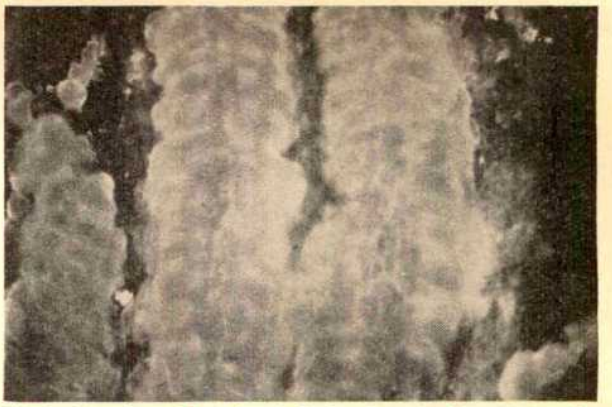

Fig. 2. Same dog as Fig. 1, longitudinal section. Positive staining with same serum (× *c.* 300)

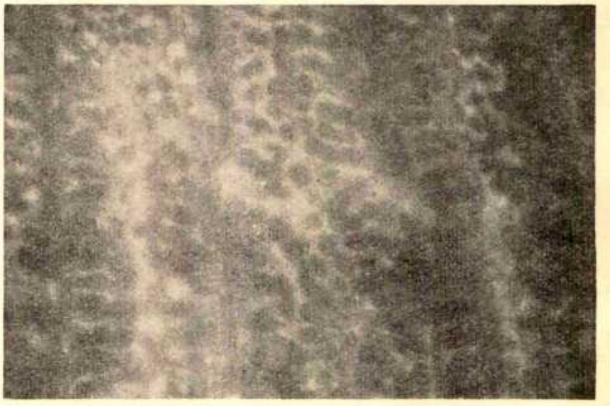

Fig. 3. Same dog as Fig. 1. Same serum after absorption on human blood group A erythrocytes. Negative staining. (× *c.* 300)

of these sera could be explained by a low titre of anti-A agglutinins, as all O and B sera with a high titre of anti-A agglutinins were constantly positive (Table 2). This similarity was confirmed by absorption investigations. The staining of animal colic glandular cells could always be abolished by previous absorption with human blood group A erythrocytes (Fig. 3), while it remained unaltered after absorption on B and O erythrocytes. On the other hand, absorption of O sera with colic tissue powder from 'positive dogs' prevented the agglutination of blood group A erythrocytes, but did not affect the agglutination of blood group B erythrocytes. Absorption with such powder from 'negative dogs' had no effect. Persistence of positive staining after absorption of sera on guinea-pig kidney powder excludes the similarity with Forssman antigen.

The antigen seems to be absent from dog erythrocytes since the absorption of sera with erythrocytes from 'positive dogs' did not prevent staining of colic glands nor agglutination of human blood group A erythrocytes. It appeared to be absent from gastric mucosa of all but one of the 13 dogs, and of all the rats and monkeys investigated. It could not be found in the salivary glands, kidney, spleen, liver or lungs of the rat.

This antigen probably belongs to the insoluble mucus fraction. Fluorescent staining coincides with periodic acid–Schiff staining of the next serial section. The antigen is left in the insoluble residue after prolonged extraction with solutions of increasing ionic strength including *C*1Na, Ca*TC* (ref. 13) and *C*12Ca, as shown by absorption investigations. The antigen could not be found in supernatant, using the technique of haemagglutination with tanned red cells[16]. Similar treatment of unfixed sections for 18 h did not prevent the fluorescent positive staining.

The data reported here indicate the presence, in colic glandular cells of rat, dog and monkey, of an antigen

cross-reacting with human blood group A substance. It is likely to exist in other animal species which were not investigated. Furthermore, our results demonstrate the absence of this antigen in the salivary glands and in all but one of the stomachs of the same animals. The fact that this antigen was found in pre-born and germ-free rats confirms the assumption that the substance is secreted by the colic glandular cells and is not a bacterial contaminant. Since blood group substances are extractable with phenol water solvents[14,15], the presence of this A-like tissue antigen should be taken into consideration in any attempt to detect specific antibodies in the sera of patients with ulcerative colitis and in any interpretation of positive results obtained with animal tissues[17].

BEND PROPAGATION ALONG FLAGELLA

By Prof. C. J. BROKAW

Division of Biology, California Institute of Technology, Pasadena

THE planar undulatory waves which are the most familiar type of flagellar movement are composed of curved regions forming circular arcs, separated by shorter unbent regions[1,2]. These waves can be generated by the propagation along the flagellum of rather abrupt transitions between straight and bent states of the flagellum. This article is concerned with the mechanism for propagating such transitions, rather than with their generation.

The most thoroughly developed model for wave propagation along flagella is that proposed by Machin[3,4], which depends on the passive wave propagating properties of the flagellum. According to this model, active bending in one region of a flagellum will cause passive bending of a more distal region of the flagellum in the opposite direction. The passive bending will be caused by viscous bending moments generated as the flagellum moves against the resistance of its surrounding medium, and will be resisted by the stiffness, or elastic bending resistance, of the flagellum. Machin suggests that the active bending elements of the flagellum can be turned on by passive bending, so that the passively propagated bend is amplified to the value characteristic of the active wave, and can then stimulate the next region in the same way. The necessary mathematical relationships between passive and active bending have been formulated in some detail, but only for small-amplitude sinusoidal waves.

It seems difficult to apply Machin's model to the non-sinusoidal waves actually found on flagella, which show no obvious passive bending in inactive regions. A more serious objection is the difficulty of applying this model to the propagation of unilateral bending waves, which involve bending in only one direction. Unilateral bending is found on flagella under some abnormal conditions[2] and appears to be the typical form of propagated bending found on cilia[5].

The activation of bending locally by passively induced bending is a most attractive feature of Machin's model, because of its simplicity. I wish to propose a new propagation mechanism which preserves this feature, while avoiding the objections raised in the preceding paragraph. It is based on the local passive propagation of bending just ahead of a transition point, and is therefore much more closely comparable with other examples of wave propagation in non-linear systems, such as the nerve axon and explosive chemical reactions.

To illustrate this proposal a rather simple and naïve model for generating flagellar bends will be adopted. It consists of a pair of longitudinal fibrils with regular cross-connexions (Fig. 1*a*). The longitudinal fibrils can contract when activated, and can resist extension and compression equally in both the contracted and elongated states. The assumption that bending results from contraction of longitudinal fibrils is popular[3,5,6] but unproved. Recent work has suggested that the conspicuous peripheral filaments seen in electron micrographs of flagella and cilia do not change their lengths during movement[2,7], but a reasonable alternative has not yet been developed. The principles involved in the proposed propagation mechanism can be generalized to other bending models, but exposition is easier with reference to a concrete model for bending.

The presence of the type of passive propagation required for this mechanism can be demonstrated roughly by the following arguments. Consider the result of activation of fibrillar contraction on one side of the segment identified by the arrow in Fig. 1*a*. If the cross-connexions are completely rigid, bending will occur as shown in Fig. 1*b*. If the cross-connexions are flexible, instead of bending there will be shear displacement within the flagellum, as shown in Fig. 1*c*. The shear resistance of the cross-connexions must actually be intermediate between these two extremes. Since the force causing shear results from

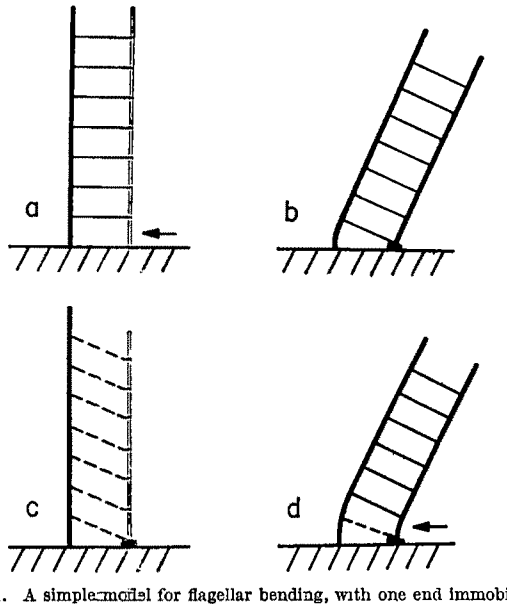

Fig 1. A simple model for flagellar bending, with one end immobilized

the difference between the longitudinal forces on either side of a cross-connexion, the force causing shear will be greatest, and therefore the greatest shear will occur, near the transition between active and inactive segments. An extreme case of such a gradient of shear is illustrated in Fig. 1*d*, where the lowermost cross-connexion is allowed to shear, while the other cross-connexions do not. With these conditions, the first two segments will bend as a unit, as shown in Fig. 1*d*, even though active contraction only occurs in the first segment. In general, then, unless the cross-connexions are completely rigid, shear will occur near the transition region, and bending will spread ahead of the region of active contraction. If bending the fibrillar segment identified by the arrow in Fig. 1*d* activates its contraction, the transition will be self-propagating.

In the following more rigorous development, the effects of the elastic forces within the flagellum will be developed first, and the viscous forces acting on the flagellum will be considered later. In a region of the flagellum which is bent to a radius of curvature, ρ, by contraction of the 'inside' longitudinal contractile fibril, there will be an elastic bending moment, M_e, equal to $2\alpha_0/\rho$, where α_0 represents the stiffness (bending resistance) of each half of the flagellum, or one of the longitudinal fibrils. M_e is equivalent to rF, where F represents a force tending to compress the 'outside' longitudinal fibril and extend the 'inside' longitudinal fibril and r corresponds to the distance between the two longitudinal fibrils.

The shear stress on a cross-connexion results from the difference between the values of F in adjacent segments along the flagellum and is therefore equal to $(\mathrm{d}F/\mathrm{d}s)\Delta s$, where s represents a measure of length along the flagellum and Δs is the distance between cross-connexions. The shear strain, S, at a cross-connexion is then given by:

$$S = \frac{1}{\alpha_2}\frac{\mathrm{d}F}{\mathrm{d}s} = \frac{2\alpha_0}{r\alpha_2}\frac{\mathrm{d}\left(\frac{1}{\rho}\right)}{\mathrm{d}s} \qquad (1)$$

where α_2 represents the stiffness (shear resistance) per unit length along the flagellum, thereby eliminating the need to include Δs explicitly.

The curvature of a segment of length Δs depends on the amount of active contraction, ΔL, of the inside longitudinal fibril in that segment; the difference, ΔS, between the shear strains at each end of the segment; and the relative compression and extension, $2\Delta C$, of the longitudinal fibrils by the force F:

$$\frac{1}{\rho} = \frac{1}{r}\frac{(\Delta L + \Delta S - 2\Delta C)}{\Delta s} \qquad (2)$$

Assuming that the cross-connexions are closely spaced, so that a treatment in terms of continuous functions is justified, this becomes:

$$\frac{1}{\rho} = \frac{1}{r}\frac{\Delta L}{\Delta s} + \frac{1}{r}\frac{\mathrm{d}S}{\mathrm{d}s} - \frac{rF}{\alpha_1} \qquad (3)$$

where α_1 represents the stiffness (bending resistance) of the whole flagellum, resulting from the resistance of the longitudinal fibrils to extension and compression. Then, from equation (1):

$$\frac{1}{\rho} = \frac{1}{r}\frac{\Delta L}{\Delta s} + \frac{2\alpha_0}{r^2\alpha_2}\frac{\mathrm{d}^2\left(\frac{1}{\rho}\right)}{\mathrm{d}s^2} - \frac{2\alpha_0}{\alpha_1\rho} \qquad (4)$$

which, after rearrangement, becomes:

$$\frac{1}{\rho} = \frac{1}{\rho_0} + \frac{1}{\alpha^2}\frac{\mathrm{d}^2\left(\frac{1}{\rho}\right)}{\mathrm{d}s^2} \qquad (5)$$

where:

$$\frac{1}{\rho_0} = \frac{\frac{1}{r}\frac{\Delta L}{\Delta s}}{1 + \frac{2\alpha_0}{\alpha_1}} \qquad (6)$$

and

$$\frac{1}{\alpha^2} = \frac{2\alpha_0}{r^2\alpha_2\left(1 + \frac{2\alpha_0}{\alpha_1}\right)} \qquad (7)$$

$1/\rho_0$ is the curvature which will result from contraction, in the absence of shear. Bending will be inefficient unless $2\alpha_0/\alpha_1$ is small compared with 1. The boundary conditions required for equation (5) are $1/\rho_0 = 1/\rho_0$ for $s < 0$ and $1/\rho_0 = 0$ for $s > 0$, and $1/\rho$ approaches $1/\rho_0$ for very large positive and negative values of s. A solution is:

$$\frac{1}{\rho} = \frac{1}{\rho_0}\left(1 - \frac{1}{2}\,\mathrm{e}^{\alpha s}\right), \qquad \text{for } s \leqslant 0$$
$$\frac{1}{\rho} = \frac{1}{2\rho_0}\,\mathrm{e}^{-\alpha s}, \qquad \text{for } s \geqslant 0 \qquad (8)$$

$1/\alpha$ represents a length constant for the exponential change of bending with distance from the point of activation at $s = 0$. This solution is illustrated in Fig. 2.

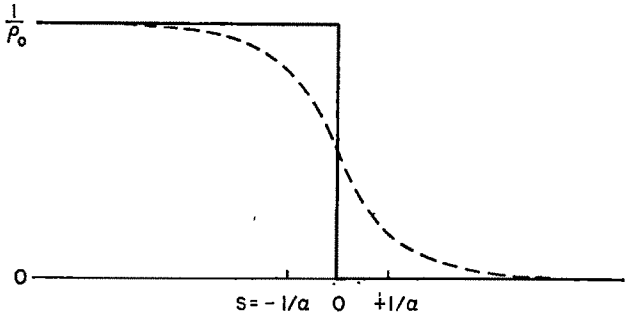

Fig. 2. Variation in curvature, $1/\rho$ (dashed line) along the flagellum near a transition point when contraction is abrupt (solid line)

The basic conclusion, that bending will spread ahead of a point of activation, does not depend on the simplification introduced by using continuous functions, as long as $1/\alpha$ is large compared with Δs. The bend will be self-propagating if contraction can be activated by bending less than $1/2\rho_0$. Since contraction at any point also tends to increase bending at that point, the system may have positive feed-back properties which increase the abruptness of the transition between unbent and bent states. However, contraction cannot be instantaneous, so the actual course of bending along the flagellum will not necessarily resemble the curve in Fig. 2.

Unbending might be activated in a similar manner if the bent elements adapt to the bent state and become sensitive to the passive unbending which will locally precede the transitions which reverse contraction. However, speculation about unbending is premature, since it is not yet known whether it is an active process similar to bending or a partially passive process which makes use of energy stored in elastic bending of part of the flagellum.

It remains to show that the bending resulting from shear, which will precede the point of activation, is significantly greater than the bending induced by viscous bending moments. The viscous bending moment, M_v, will enter by adding to the force F, so that:

$$rF = M_e + M_v \qquad (9)$$

Two additional terms must then be added to equation (4):

$$\frac{1}{r^2\alpha_2}\frac{\mathrm{d}^2M_v}{\mathrm{d}s^2} - \frac{M_v}{\alpha_1}$$

Since M_v varies almost sinusoidally along the length of the flagellum[2], with the periodicity given by the length L, its second derivative can be approximated by:

$$-\left(\frac{2\pi}{L}\right)^2 M_v$$

Using equation (7), the contribution from M_v then becomes:

$$-\left[\frac{\left(1+\frac{2\alpha_0}{\alpha_1}\right)}{2\alpha^2\alpha_0}\left(\frac{2\pi}{L}\right)^2+\frac{1}{\alpha_1}\right]M_v$$

For sea-urchin spermatozoa, L is approximately 9π μ (ref. 2), and the length constant, $1/\alpha$, is 1μ or less. With these values, the contribution from M_v becomes:

$$-\left[\frac{1+\frac{\alpha_1}{2\alpha_0}}{20}+1\right]\frac{M_v}{\alpha_1}$$

Since α_0 represents the stiffness of half the flagellum and α_1 represents the stiffness of the whole flagellum, their relative values depend on the relationships of structures in the cross-section of the flagellum. If the distribution of stiffness in a flagellum resembled that of a homogeneous cylindrical rod, α_1/α_0 would be about 7. Other distributions could increase this ratio, but it is unlikely to exceed 20. The contribution from M_v will therefore be no greater than $\frac{3}{2}\frac{M_v}{\alpha_1}$ and will be closer to M_v/α_1 if the length constant, $1/\alpha$, is small.

As pointed out previously[2,8], the constancy of circular curvature in the bent regions of a flagellum and the very slight amount of noticeable passive bending in the straight regions of a cilium or flagellum indicate that M_v/α_1 is small compared to $1/\rho_0$. The passive bending induced by viscous forces will therefore be significantly smaller than that resulting from shear strain near the transition regions. It may not, however, be completely negligible, in which case the properties of Machin's model might also be involved in controlling wave propagation.

One of the main arguments offered in support of Machin's model is the occurrence of synchronization between flagella which come into close proximity[4]. However, this implies no more than that wave propagation is sensitive to the resistance to movement offered by the environment, which is also shown under conditions such as increased viscosity[2,9]. This sensitivity can lie either in the passive disturbance which is responsible for activation or in the time-course of contraction following activation, since both will be involved in determining the propagation velocity. Since the mechanism proposed here still allows environmental factors to influence the time-course of contraction following activation, and therefore the propagation velocity, it can be adapted to fit observations of synchrony and the effects of increased viscosity.

In addition to the points raised at the beginning of this paper, there are several possible experiments which may discriminate between Machin's model and a model involving local spread of bending such as the one proposed here. Some of these are under way in our laboratory. It will be more difficult to distinguish experimentally between the model proposed here and models involving other types of locally spreading signals. However, the preservation of wave propagation in ATP-reactivated, glycerinated flagella which have lost their normal membrane properties[10,11] and the sensitivity of propagation velocity to viscosity and other mechanical factors, argues in favour of a very simple type of locally spreading signal, such as the one proposed in this article.

IMMUNOLOGICAL TOLERANCE OF NEONATALLY INFECTED MICE TO THE MOLONEY LEUKAEMIA VIRUS

By EVA KLEIN and GEORGE KLEIN

Department of Tumour Biology, Karolinska Institutet Medical School, Stockholm, Sweden

TISSUE preparations containing the Moloney virus are capable of inducing a state of specific host resistance against the transplantation of small Moloney lymphoma isografts[1,2]. Concomitantly, serum antibodies appear which react specifically with Moloney lymphoma target cells in the cytotoxic and the fluorescent antibody tests and can also neutralize the leukaemogenic and immunogenic properties of the virus[2,3]. Transplantation resistance and serum antibodies can be readily induced even by highly diluted preparations of virus-containing material and, once attained, high antibody titres persist throughout the lifetime of the recipient. Mainly for this reason, we have postulated[3] that multiplication of the inoculated virus is mostly responsible for host immunization. It could not be decided, however, whether the rejection response and the concomitantly developing anti-target-cell antibodies are due to the antiviral response as such, or are mediated via new 'cellular' antigens, induced by the virus but different in specificity from the antigens of the mature virion, as in the polyoma and the Rous systems[4,5]. This distinction could only be made if lymphoma lines could be isolated which do not release any infectious virus.

With one notable exception, inoculation of leukaemia virus containing materials to adult mice has led to transplantation resistance and antibody formation regularly in all virus-host-tumour systems examined. The exception is represented by the high-leukaemia strain *AKR*, known to transmit the Gross virus vertically from parent to offspring. Lymphomas developing in this strain carry the same specific antigen(s) as Gross virus induced lymphomas of other strains, but neither *AKR* nor *AKR* × *C3H* F_1 mice respond to active immunization, and they fail to develop humoral (cytotoxic) antibodies or transplantation resistance after attempts at active immunization[6–8]. This suggests that they are tolerant to the agent, and, if it is a different entity, also to the 'cellular' antigen(s) induced by it. This interpretation is confirmed experimentally by the finding that *C3H* mice infected with the Gross virus neonatally could not be made resistant against the isotransplantation of Gross lymphoma cells, even if re-infected at an adult age, in contrast to *C3H* mice infected as adults[6]. Closely similar findings have been obtained with the Moloney agent. Adult mice infected with this virus regularly attain a state of specific transplantation resistance which is much stronger[2], as a rule (that is, protects from a large number of grafted neoplastic cells), than what can be obtained in analogous experiments with the Gross system[9]. Humoral antibodies are also regularly present in higher titres and can be demonstrated not only by the cytotoxic but also by the fluorescent antibody method. In contrast, mice inoculated as new-born

either entirely fail to react or show a deficient or delayed antibody response[10].

The work recorded here represents a further attempt to understand this tolerant state. It was tested whether neonatally infected mice which lack demonstrable antibodies can respond immunologically to a second virus challenge as adults and whether their non-responsiveness against cellular targets as revealed by the fluorescence test is paralleled by a similar deficiency in virus neutralizing ability. In addition, whether they were capable of rejecting small isografts from established Moloney lymphomas, known to be susceptible to the rejection reaction of virus inoculated adult mice, was investigated.

Antibodies directed against cellular targets were detected by the immunofluorescence test as applied to living cells[2,11]. The *YLD* lymphoma, induced by the Moloney agent in a *C57L*eaden mouse, was used as the standard target cell. The sera were tested for virus neutralizing activity by adapting the mouse antibody production (MAP) assay for the virus[3]. 0·1 ml. 1 : 100 diluted standard virus preparation was inoculated into *2A* × *CBA* F_1 or *ABY* × *CBA* F_1 mice after incubation with 0·05 ml. undiluted test or control serum for 4 h at room temperature. The sera of the recipient mice were tested for antibodies by the immunofluorescence test against *YLD* at appropriate intervals.

Fig. 1 illustrates the results of one experiment. Eight new-born (less than 24 h old) *A* mice, derived from two litters, were inoculated with 0·05 ml. of a 1 : 10 diluted virus preparation. Three adult *A* mice were inoculated simultaneously. The mice were bled individually and their sera were tested against *YLD* target cells in the immunofluorescence test. While sera of all mice injected as adults were highly positive 30 days later, none of the neonatally infected animals had significant antibody levels. Six in the latter group developed leukaemia 103, 103, 117, 158, 165, and 178 days after inoculation. The four neonatally infected mice that were negative on day 160 were re-infected with 0·05 ml. 1 : 10 diluted virus preparation on that day. Five previously untreated *A* mice of the same age were infected at the same time. Two of the four mice of the former category died with leukaemia before their serum could be collected for test. The other two could be tested and were found to remain negative during the entire observation period, that is, 205–270 days after the first and 45–90 days after the second virus dose. One died with leukaemia at the age of 220 days. The control mice which were infected as adults produced antibodies

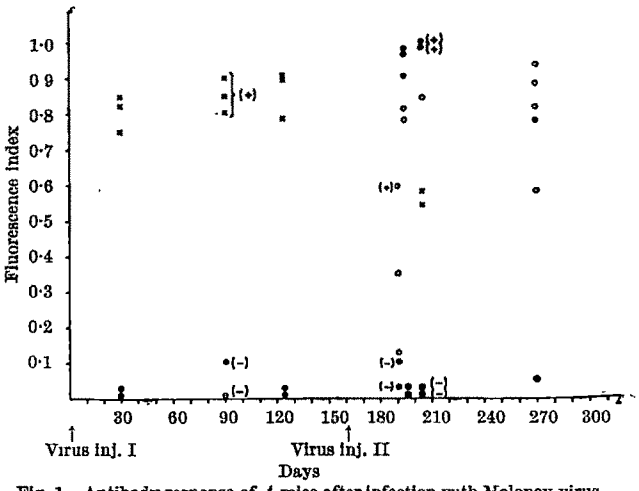

Fig. 1. Antibody response of *A* mice after infection with Moloney virus. ●, Two *A* mice (1♂ and 2♀) infected neonatally and re-infected on day 160; ×, three *A*♂ mice (3, 4 and 5) infected as adults on day 160; ○, five *A*♀ mice (including 6, 7 and 8) infected as adults on day 160. Antibodies were measured against *YLD* target cells by the immunofluorescence test and were expressed by the fluorescence index (+); and (−) denotes the results of virus neutralization tests performed with the same serum (cp. Table 2)

and maintained them in a high titre during the entire observation period of several months.

In order to test the responsiveness of the neonatally infected animals against an unrelated antigen, 0·1 ml. of a 25 per cent suspension of sheep red cells was injected at day 210 to the two non-reacting mice. Four days later the serum haemolysin titres were 1 : 320 and 1 : 640. Simultaneously injected controls gave 1 : 640; 1 : 1,280; 1 : 640 and 1 : 160, respectively. Thus the two non-responsive animals were capable of reacting against an unrelated antigen.

Table 1 shows further experiments of a similar design, performed with *A*, *C57L*eaden and *C3H* mice. Among the mice infected neonatally with the virus, all 5 *C3H*, all 15 *A* and 6 of 10 *C57L*eaden showed a deficient antibody response after 110–120 days. As in our previous work, the fluorescence index (FI) = 0·30 was taken as the threshold for a significantly positive reaction. Fourteen non-reactive mice were chosen for the experiments summarized in Table 1. When re-infected with a second virus dose at adult age, between 120 and 160 days, none of them responded with detectable antibody formation.

* 0·1 ml. 1 : 100 dil. standard virus preparation was inoculated to each mouse after incubation with 0·05 ml. undiluted test serum during 4 h at room temperature. Prior to inoculation 0·1 ml. balanced salt solution was added. Two adult *A* × *CBA* F_1 mice served as recipients in Exp. *A*, two *ABY* × *CBA* F_1 mice in Exp. *B*, and two *ABY* × *CBA* F_1 in Exp. *C*.

Some of the sera were also tested for virus neutralizing activity. On the basis of our previous experience[3], this was appraised by testing their ability to neutralize or reduce the antibody-inducing capacity of standard virus-containing homogenates. The results are given in Table 2. Three separate experiments were performed. They include two standard post-infectious sera of adult mice, collected 7–8 months after inoculation and with a positive known FI value. These served as positive controls for virus neutralization while normal mouse serum was used as a negative control. It appears that both standard Moloney antisera (pools 5313 and 3960) showed a clear neutralizing activity. The same was true for the sera of 5 mice infected as adults and for the sera of two neonatally infected *A.SW* mice that had high FI values. All 18 sera collected from 10 neonatally infected mice which gave a negative FI when tested directly against lymphoma target cells were also negative when assayed for virus neutralizing ability. Taken together, all tests thus show a clear inverse relationship between the FI of the serum admixed to the virus containing homogenate and the antibody level of the mice inoculated with the mixture and tested 33–45 days after inoculation.

Table 3 shows the results of the tests carried out to compare the ability of neonatally infected mice to reject small Moloney lymphoma isografts with animals infected as adults and untreated controls. The *YLD* lymphoma, previously found highly susceptible to the rejection response of syngeneic hosts infected as adults, was used for these tests as well. It appears that while all mice infected as adults rejected the grafts which grew regularly in untreated controls, mice infected as new-born were susceptible in 18 of 21 cases. Among the three resistant mice, two had positive antibody titres at the time of tumour cell challenge while all 18 susceptible animals were negative at the same time.

In conclusion, the non-responsiveness of neonatally infected mice after re-infection at adult age fulfils the operational criteria of immunological tolerance. The parallel presence or lack of the virus neutralizing and the anticellular activity of the various sera may be due to the identical specificity of the antibodies involved. This is particularly suggestive in view of the strictly parallel individual variation in the response of different neonatally infected mice in relation to the different test systems. Since tolerance may have been induced to more than one antigen at the same time, however, this evidence is merely suggestive but not conclusive.

MAGNESIUM NUTRITION OF COTTON AS INFLUENCED BY SODIUM

By MERVYN W. THENABADU*
Department of Agriculture, Peradeniya, Ceylon

THE beneficial effects of sodium fertilization on the growth and yield of cotton have been reported by many investigators[1–5]. Several concluded that the best returns from sodium were obtained on soils deficient in potassium, and only in a few cases have physiological and nutritional reasons been advanced to explain the results. Mathews[5] attributed the yield increase in cotton to the effect of the sodium ion in partially substituting the potassium ion in some of its metabolic functions. Appling and Giddens[6] found that the contents of sodium and potassium in the various parts of the plant were directly proportional to the amounts of these elements applied as fertilizers, and that sodium accumulated in the upper leaves. They concluded that the preferential shift of potassium to the active meristematic regions indicated that sodium probably performed some of the functions of potassium in the

* Present address: Department of Soils and Plant Nutrition, University of California, Davis.

Table 1. DRY WEIGHTS (g) OF 85-DAY-OLD COTTON PLANT FRACTIONS AS INFLUENCED BY MAGNESIUM AND SODIUM

Treatments	Young leaves	Old leaves	Young stems	Old stems	Roots	Squares	Bolls

more mature tissue. Joham[7] established the ability of sodium to partially substitute for both potassium and calcium in their general cationic functions in the cotton plant. Sodium had a significant influence on 90-day-old cotton plants growing in nutrient solutions deficient in either calcium or potassium during the latter half of their growth.

While sodium was found to influence fruiting activity when either calcium or potassium was withheld, it also prevented wilting in plants grown in low calcium solutions. It was suggested that sodium probably mobilized stored calcium from the older tissue, but it had no influence on the movement of potassium. The results of further investigations suggested a role of sodium in maintaining a favourable protein status in plants deficient in potassium[8]. The level of leaf protein was related to the level of substrate potassium and sodium. Plants deficient in both cations had the lowest concentration of protein, while no significant differences were seen in those receiving either sodium or potassium.

The investigation recorded here was undertaken in the autumn and winter of 1962–63 as a logical extension of the problem of sodium substitution for the macronutrient cations in cotton nutrition.

Cotton seeds, variety 'Deltapine 15', were germinated in flats of sterilized perlite. Six days after emergence three uniform seedlings were washed free of perlite and transplanted into each of twenty plastic 6-litre pots containing the following nutrient solution: $Ca(NO_3)_2.4H_2O$, 5 mM; KNO_3, 3 mM; $(NH_4)_2SO_4$, 2 mM; K_2HPO_4, 11 mM; $MgCl_2.6H_2O$, 2 mM. The micronutrient elements supplemented to each pot consisted of 2 p.p.m. ferric iron, 0·5 p.p.m. each of manganese and boron, 0·05 p.p.m. zinc, 0·04 p.p.m. molybdenum and 0·03 p.p.m. copper. The solutions were aerated from a central source and the *p*H of the solutions was checked daily and adjusted if necessary by the addition of dilute nitric acid or ammonium hydroxide to maintain the range *p*H 5·0–6·0.

Four treatments were started thirty days after transplanting: (*a*) plus magnesium–plus sodium (+Mg +Na); (*b*) plus magnesium–minus sodium (+Mg −Na); (*c*) minus magnesium–plus sodium (−Mg +Na); (*d*) minus magnesium–minus sodium (−Mg−Na). $MgCl_2$ was eliminated from the −Mg series and NaCl (10 mM/l.) was added to the +Na series. The experimental design was a randomized block with five replications on the greenhouse bench.

Harvests were made 60 and 85 days after transplanting. At the 85-day harvest the leaves and stems were separated into old and new growth tissue, the latter being the growth made between 60 and 85 days. The tried, ground plant samples were ashed in a muffle furnace at 500° C and then dissolved in 5 per cent hydrochloric acid. Magnesium, sodium, potassium and calcium were determined using a Beckman *DU* spectrophotometer with a flame attachment.

Incipient magnesium deficiency symptoms were observed 12 days after the treatments were effected. Plants not receiving magnesium exhibited an interveinal chlorosis on the recently matured leaves. The interveinal areas gradually turned reddish brown in colour during the next 20–30 days, and the areas spread and coalesced. Stunted growth and shedding of flower buds were characteristic of the magnesium deficient plants

The addition of sodium to plus and minus magnesium solutions had little or no effect on the growth of cotton as indicated by dry weights (Table 1). However, in this experiment, sodium had a beneficial effect on the development of plants supplied with magnesium. Plants of the +Mg+Na treatment flowered earlier and produced more flowers than those of the +Mg−Na treatment.

It is apparent that substrate sodium had a marked influence on the distribution of magnesium in the cotton plant. Comparison of data in the +Mg+Na and +Mg −Na series at the 60-day harvest (Table 2) shows a decrease in magnesium content in the roots and stems with a corresponding increase in the leaves due to sodium. By the 85-day harvest sodium had little or no effect on stem and leaf magnesium in the +Mg plants although the trend observed in root magnesium at 60 days was still evident. In the −Mg series at the 60-day harvest differences in magnesium content in the tissue due to substrate sodium were not significant. However, there were significant magnesium–sodium interactions in all cases. By 85 days all the above-ground organs of the −Mg+Na plants contained higher tissue magnesium than corresponding parts of the −Mg−Na plants.

Thus it appears that sodium in the substrate may serve some function in the maintenance of magnesium. This was apparent in the +Mg plants at the early harvest and in the −Mg plants at the final harvest. An inverse relation was noted between root magnesium and substrate sodium at both harvests.

Marked diurnal variations of the magnesium content in the leaves of the cotton plant have been reported[9], and the mobilization of magnesium to the active growing points has been shown with other plants[10,11]. In this investigation the indications are that sodium in the substrate enhances this phenomenon, releasing the magnesium from the older tissue, thus enabling it to be re-utilized in the younger more active areas. If this is the case the possibility exists for the partial substitution of sodium for magnesium in the nutrition of the cotton plant. In this investigation the deficiency of magnesium was very severe and it may be that beneficial effects of sodium in the −Mg series were not evident at that level of magnesium nutrition. Support for this concept was evidenced in the flowering response of the +Mg plants to the additions of sodium. It may be that earlier flowering of the +Mg+Na plants was due to the greater movement of magnesium to the active growing tissues.

In stems and roots, tissue sodium was inversely related to substrate magnesium at the 60-day harvest. At 85 days substrate magnesium tended to decrease tissue sodium in roots and stems and increase sodium in the leaves (Table 3).

In the 60-day-old plants the distribution of potassium in the roots and stems was effected by significant magnesium–sodium interactions. In the −Mg series the +Na plants contained a significantly higher amount of potassium in the leaves than those of the −Na treatment (Table 4). The same trends were evident in the young leaf and young and old stem of the 85-day-old plants of

the −Mg series. These results indicate that plants growing in a nutrient medium deficient in magnesium absorbed more potassium in the presence of sodium, thus suggesting another beneficial effect of sodium under conditions of nutrient impoverishment.

In general, plants growing under conditions of magnesium deficiency contained more calcium in their tissue than those with an adequate magnesium supply (Table 5). This is in agreement with the concept of the cation equivalency in plants[12,13]. The distribution of calcium in some tissues was also subject to significant magnesium–sodium interactions. In the stems of the 60-day-old plants, the presence of sodium in the substrate increased the calcium content when magnesium was supplied, while the opposite effect was observed in the absence of substrate magnesium. In the roots of the 60-day-old plants substrate sodium was associated with an increase in tissue calcium regardless of magnesium treatment. In the −Mg treatments of the 85-day-old plants, substrate sodium depressed the calcium content in all tissue except the roots and old stems. The calcium contents in the old and young leaves of the −Mg−Na treatment were significantly less than those of the −Mg−Na treatment. In the presence of magnesium, however, sodium increased the calcium content in all tissue. While these findings are in agreement with those of Joham[7,14] they are contrary to those of Cooper *et al.*[2].

Thus it was found that under certain conditions sodium increased the magnesium, potassium and calcium contents in the cotton plant. In some cases the effect of sodium was even more pronounced under conditions of magnesium deficiency. In addition significant magnesium–sodium interactions were found to govern the uptake and accumulation of macronutrient cations. The results suggest that under conditions of magnesium deficiency, sodium enhanced the mobilization of magnesium from the older to the more actively growing tissues.

This investigation was carried out at Texas A and M University. I thank Prof. H. E. Joham for his advice.

CELL DISPERSING LIVER EXTRACT INFLUENCING BLOOD CLOTTING

By KARL E. FICHTELIUS and BIRGITTA KULLGREN
Department of Histology, University of Uppsala, Sweden

AFTER the addition of a cell-free liver extract to suspensions of thymus or lymph node cells in Earl's solution, the number of cells per mm³ was more than 200 per cent of the number of cells per mm³ after the addition of Earl's solution[1]. (This effect with the liver extract occurred immediately.) Experiments with pipettes of different diameters support the view that the liver factor contributes to the dissolution of cell aggregates in the suspension. It has been concluded that the addition of liver extract may be a useful method by which the

correct cell number in suspensions of lymphoid cells can be obtained, and the degree of aggregation in such suspensions can be estimated.

This communication reports experiments using similar liver extracts. Our first question was: Is liver extract more effective than extracts of other organs in preventing the formation of aggregates of thymus cells?

Homogenates of liver, spleen, kidneys, small intestines, lungs, muscles and testes (one part of the organ to two parts of Earl's solution) were prepared from guinea-pigs weighing approximately 200 g. The homogenates were centrifuged for 20 min at 2,500*g*; the supernatant fluids were the extracts used. They were kept at 4° C and used within 72 h of preparation. Serum was diluted with two parts of Earl's solution, stored and used in the same way as the extracts.

Thymus suspension was prepared as follows: the thymus from a guinea-pig was roughly freed from connective tissue, washed in Earl's solution, and stored in a moist chamber at 4° C for 4 h. The surface was then carefully freed from remaining connective tissue and the thymus washed once more. The organ was then cut up finely in 3 c.c. of Earl's solution, and the pieces stirred with a pair of forceps and pressed against the sides of the glass vessel. Another 3 c.c. of Earl's solution was added and the tissue mixture was then sieved through ordinary muslin. 0·025 c.c. portions of Earl's solution, of organ extract, and of diluted serum were placed in test-tubes. As soon as the cell suspension was prepared, 0·5 c.c. was quickly added to each tube with a 5 c.c. pipette. The mixtures were gently rocked for 1 h at room temperature, and the number of cells per mm³ counted. The cell counts were converted to relative numbers (the highest count per mm³ = 100). Five tests were performed.

The highest cell count was found in the mixture with liver extract in all experiments, and the lowest cell count was found in the mixture with Earl's solution (Table 1). This indicates that the liver extract was the most effective in preventing aggregate formation and that the aggregate-preventing factor or factors were present in all extracts and the serum.

Table 1. Relative No. of Cells per mm³ in Different Mixtures

	1	2	3	4	5	Mean
Susp. + Earl's	48·9	36·9	51·3	46·6	22·0	41·1

Susp. + Earl's	46·9	47·7	32·0	54·8	28·2	41·9

The earlier findings[1] and the results obtained as described here suggested that a factor is normally formed or stored in the liver which is necessary for the natural suspension of blood cells. Some preliminary experiments on thrombocytes in peripheral blood are reported here.

Homogenates of liver were prepared as already described, but from human liver. The supernatant after the first centrifugation was centrifuged for 1 h at 100,000*g*. After discarding the floating material the new supernatant was the extract. This was kept at 4° C, and used within 5 days following the first centrifugation.

The number of thrombocytes per mm³ were counted from: (*a*) heparinized blood 10 min after sampling; (*b*) the liver extract used; (*c*) a mixture of 0·5 c.c. heparinized blood and 0·5 c.c. liver extract after rocking for 1 h in room temperature; (*d*) a similar mixture of 0·5 c.c. heparinized blood and Earl's solution.

It is evident from Table 2 that the liver extract used was not free from particles, probably bacteria. With the method used, these would have been counted as thrombocytes. The dilution solution used for counting and the Earl's solution did not contain such particles. However, it is quite easy to make a correction for the presence of

Table 2. No. of Thrombocytes per mm³ in Different Mixtures

Table 3. Corrected No. of Thrombocytes in Different Mixtures

	Heparinized blood	Blood + liver extract	Blood + Earl's solution
(1)	244,000	396,000	127,200
(2)	254,000	288,000	189,600
(3)	201,200	274,400	134,400
(4)	182,000	329,600	72,800
(5)*	253,600	332,800	80,800
(6)*	258,800	333,600	92,000
(7)†	206,000	87,200	43,200
(8)†	220,000	187,200	70,400
(9)†	193,600	107,200	104,000
(10)	196,000	233,200	97,600
(11)	223,200	221,200	65,600

* The liver extract was stored at +4° C for 5 days.
† The liver was stored at +4° C for 2 days before the extract was prepared.

such foreign particles. Corrections were made, at the same time, for the dilution 1 : 2 in *c* and *d*: these are given in Table 3.

The correction formulae are: Corrected figure for the blood–liver extract mixture =

$$2 \times \left(\text{figure obtained} - \frac{(\text{figure for liver extract})}{2} \right)$$

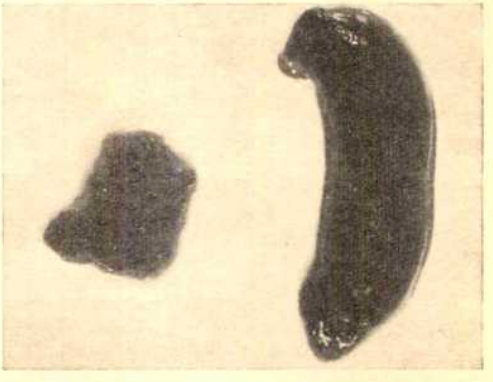
Corrected figure for the blood–Earl's solution mixture =

$$2 \times \text{figure obtained}$$

The blood–Earl's solution mixture shows lower figures than the blood alone, which indicates the presence of aggregates, or loss of cells on the glass walls in this mixture. The blood–liver extract mixture shows higher figures than the blood alone. This indicates that there is a certain degree of aggregate formation or loss of cells on the glass walls already in the heparinized blood.

The ability of the liver extract to influence the suspension stability or the adhesiveness of thrombocytes suggested that it might be involved in the formation of blood clots. The following experiments were designed in order to test this possibility.

Whole blood of various species was mixed with equal parts of Earl's solution or with liver extract from different species. The liver extract was prepared as in the first experiment. The mixtures were gently rocked for 1 h at room temperature. Smears were prepared from the mixtures and examined histologically for the degree of



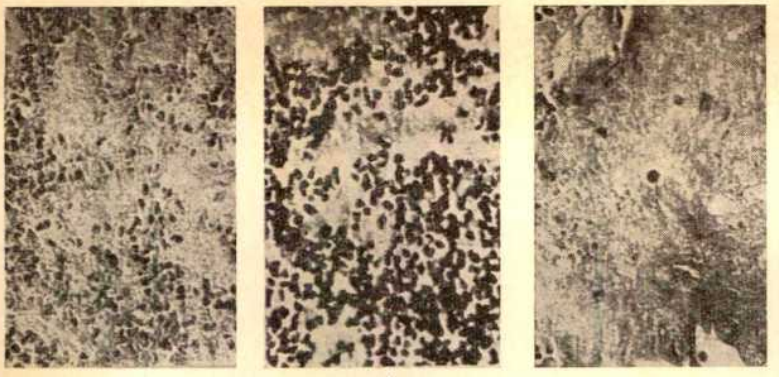


Fig. 1. Blood from guinea-pig. To the left, clot formed by rocking with guinea-pig liver extract. To the right, clot formed by rocking with Earl's solution

a *b* *c*

Fig. 2. Blood from National Institutes of Health New Zealand albino rabbit (× 140). (*a*) Clot formed on rocking with guinea-pig liver extract. (*b*) Clot formed on rocking with Earl's solution. (*c*) Clot formed on shaking with Earl's solution (defibrination)

erythrocyte aggregation. After rocking, the clots were observed and a few were embedded and sectioned for routine histological examination. The sections were stained according to Weigert (Romeis 1948, § 1424). In one case a blood–Earl's solution mixture was shaken vigorously in a relatively large vessel for defibrination.

The following combinations of blood and liver extract were tested: (1) blood from National Institutes of Health New Zealand albino rabbits with guinea-pig liver (5 tests); (2) blood and liver from guinea-pigs (7 tests); (3) blood from Swedish farmer's rabbits with guinea-pig liver (2 tests); (4) blood from National Institutes of Health New Zealand albino rabbits with human liver (1 test); (5) human blood with human liver (4 tests); (6) blood and liver from Swedish farmer's rabbits (2 tests).

In three of the combinations tested (1, 2 and 4) there was a clear-cut difference between the clots: the clot in the mixture with Earl's solution was an ordinary clot containing numerous red cells, but in the mixture with liver extract the clot was small and pale, containing relatively few red cells (Fig. 1). Histological examination revealed that the pale small clot obtained with liver extract in combination (1) was a fibrin clot resembling the clot at defibrination (Fig. 2). The smears from these combinations (1, 2 and 4) did not reveal differences in the size of red cell aggregates in the mixtures with liver extract or those with Earl's solution.

In other combinations performed (3, 5 and 6) there were no similar differences between the clots.

It is of limited value to discuss at this early stage the liver factor or liver factors. It will suffice to say that there may be something of great biological interest hidden here. The factor preventing the thrombocyte aggregation may also be of clinical interest. Without doubt, addition of liver extract can be recommended as a method for obtaining a correct cell number in artificially prepared suspensions. The liver extract has been shown to prevent the formation of aggregates in suspensions of bone marrow cells[2]. Furthermore, serum has been shown to split aggregates of sarcoma cells[3].

CONTROL OF SELF-IRRADIATION DECOMPOSITION OF TRITIUM-LABELLED COMPOUNDS AT HIGH SPECIFIC ACTIVITY

By Dr. E. ANTHONY EVANS
The Radiochemical Centre, Amersham, Buckinghamshire

THE increasing use of tritium compounds as tracers at very high specific activity (some examples, refs. 1–3) has presented growing problems to both supplier and user in minimizing the rates of decomposition of these compounds on storage.

Since publication[4] of the first extensive examination of the decomposition of tritium compounds, several investigators have published their observations of the self-decomposition of groups of tritium compounds such as amino-acids[5,6], steroids[7] and fatty acid esters[8], or of specific tritium compounds such as thymidine[9,10], chimyl alcohol[11], *cyclo*hexane[12] and *n*-propanol[12]. Methods adopted to control decomposition rates have included, for example, storage in various solvents[4–6,12], dispersal on paper[5,6] and on various solids[12], such as charcoal, benzanthracene, silica gel, cellulose and ferric oxides, low-temperature storage (−196° C)[10], the use of radical scavengers[9,10] for compounds stored in aqueous solution, and the inclusion of tritium compounds as clathrates[13]. It is doubtful whether decomposition can be eliminated completely by any method. One answer to the problem is, of course, to use the compound immediately after purification, but this is not always practicable or economical, and better methods for reducing the rates of decomposition to a tolerable level are still needed.

This article presents preliminary results of the investigation of two important aspects of the control of the decomposition of tritiated organic compounds from self-irradiation on storage. These are: (1) use of radical scavengers for compounds stored in aqueous solution; (2) storage at very low temperatures (−196° C). Both these methods have been found to reduce substantially the rate of decomposition as illustrated by the examples given in Tables 2 and 3.

Use of Radical Scavengers

The protective action of benzyl alcohol[9] or cysteamine[10] against radiation decomposition for compounds in aqueous solution has previously been mentioned. To be effective in reducing the rate of self-decomposition of tritium compounds stored in aqueous solution, additives must effectively and efficiently 'scavenge' hydrogen and hydroxyl radicals, which arise by radiolysis of the water[14].

Three compounds were selected for detailed investigation:

(*a*) *Benzyl alcohol*, which has also the advantage of being a bacteriostat. It is not easily removed, however, and furthermore it can give rise to aldehydes, phenols and acids by interaction with H and OH radicals[15]. Although these radiolysis products should not be radioactive (assuming there is no hydrogen–tritium exchange and no interaction with labelled species), their presence may be undesirable for some investigations.

(*b*) *Ethyl alcohol*, which is easily removed and, at the low concentrations normally required (less than 5 per

cent), is unlikely to produce side-effects in research investigations. Disadvantages include the formation of aldehydes and glycols by reaction with free radicals[15], and the presence of alcohol may actually accelerate the rate of decomposition of the solute[16,22]. Under some storage conditions esterification of the solute can occur[5,6].

(c) *Sodium formate (or formic acid)*. The effects of radiation on aqueous solutions of formic acid are among the reactions of this type that have been subjected to most intensive investigation[15]. The main products from the interaction of formate with H or OH radicals are carbon dioxide and water:

$$\cdot H + HCOOH \rightarrow H_2 + \cdot COOH$$

$$\cdot OH + HCOOH \rightarrow H_2O + \cdot COOH$$

$$2 \cdot COOH \rightarrow HCOOH + CO_2$$

Net reaction

$$HCOOH \rightarrow H_2O + CO_2$$

Thus, during the course of its protective action, the formate concentration is likely to decrease giving water and carbon dioxide. There would seem no obvious disadvantages in the use of formate as a radical scavenger, except, of course, when the tritiated compound is to be used in a system which must be free of formate. For many classes of labelled compound it could be removed fairly easily.

Scavenging Efficiencies

To compare the scavenging efficiencies of benzyl alcohol, ethyl alcohol and formate, solutions of thymidine-2-^{14}C (specific activity 18·3 mc./mmole) at 10 μc./ml. containing the scavengers in concentrations ranging from 0·001 per cent to 1 per cent were irradiated with γ-rays to a total dose of 2·5 megarads. The degree of protection, as measured by the amount of thymidine-2-^{14}C surviving (determined chromatographically)[9], is shown in Table 1.

Table 1. The Effect of γ-irradiation* on Solutions of Thymidine-2-^{14}C containing Free Radical Scavengers

Scavenger	Concentration (per cent)	Degree of protection
None (controls)	—	Nil
Benzyl alcohol	1	90–95 per cent
Benzyl alcohol	0·001	Approximately 50 per cent
Ethyl alcohol	0·001–1	Nil
Sodium formate	0·001–1	Nil

* For these irradiations I thank the Irradiation Service, U.K. Atomic Energy Authority, Harwell, Berkshire.

These results indicate that neither ethyl alcohol nor sodium formate was effective in protecting the thymidine-2-^{14}C and only benzyl alcohol at 1 per cent concentration afforded a high degree of protection. The results are interpreted to suggest that both ethyl alcohol and formate react rapidly[20,21] with the free radicals produced by the γ-rays and that these compounds did not survive long enough to protect the thymidine. Benzyl alcohol, on the other hand, containing the aromatic nucleus is much more resistant to destruction[15] and afforded a better protection for the thymidine-2-^{14}C. Provided sufficient ethyl alcohol or formate were present in solutions of tritiated compounds, these two scavengers, which readily interact with the free radicals, should provide a high degree of protection and substantially reduce the rate of decomposition of the tritiated compound.

In Table 2 are shown results obtained on keeping selected tritiated nucleosides and amino-acids of high specific activity in solutions containing benzyl alcohol, ethyl alcohol or sodium formate as radical scavengers.

The results show that all three scavengers are effective in reducing the rate of self-irradiation decomposition of the tritium compounds, but the efficiency of formate, even at concentrations of 0·01 per cent, is particularly interesting. Compared with the controls the rate of decomposition is reduced almost by an order of magnitude; thus the $G(-M)$ value for tyrosine, labelled in the 3 and 5 positions of the benzene nucleus at a specific activity of 48 c./mmole, is reduced from 0·27 in the controls to 0·03 when stored in 0·1 per cent sodium formate solution. For the nucleoside uridine labelled specifically in the 5-position of the pyrimidine moiety, the $G(-M)$ value in the controls (0·67) is reduced to 0·17 in solutions containing 0·01 per cent sodium formate. In the examples investigated, ethyl alcohol appears only slightly more effective than benzyl alcohol.

It should be remembered that these additives are chemical impurities. The value of additives as radical scavengers for retarding the rate of self-irradiation decomposition for tritium compounds in solution should be balanced against their possible effects in any investigation. Although the scavengers are present in low chemical concentrations, this will often exceed the concentration of the tritiated compounds, especially for those compounds at very high specific activity.

The use of additives (free radical scavengers) to control decomposition promises to be a most useful, practical and convenient method for minimizing the decomposition of tritium compounds stored in aqueous solution at high specific activity.

It is interesting to note also that L-tyrosine-3,5-T racemizes on storage in solution, even in the presence of formate as radical scavenger. This effect, which has been observed also with aqueous solutions of other tritiated amino-acids (L-leucine-4,5-T; L-phenylalanine-4-T; and L-methionine-T(G)), is under further investigation[17], but preliminary results suggest that this phenomenon may be induced by β-radiation.

Storage of Tritium Compounds at −196° C

Storage of aqueous solutions of tritiated thymidine at −196° C was first examined by Apelgot *et al.*[10]. Their results indicated that the rate of decomposition was substantially reduced at this very low temperature. The rates of decomposition of a number of tritiated compounds stored at −196° C have now been examined and the results are shown in Table 3.

Storage of freeze-dried tritium compounds tends to give rather erratic results, the rate of decomposition depending on how the material is spread on the surface of the glass tube. Note, for example, the difference between a 0·25 mc. (containing 18·5 μg) and a 1-mc. (containing 74 μg) ampoule of folic acid-3′,5′-T. Although the rate of decomposition of tritium compounds stored in the solid state is reduced at −196° C, it is still, nevertheless, substantial and in general the use of a protecting solvent is necessary[4].

The rate of decomposition of tritium compounds in aqueous solution increases as the dose per unit time is increased, that is, as the activity concentration per ml. is increased (at constant specific activity). It is interesting to note, however, that at −196° C the decomposition rate for tetrasodium 2-methyl-1,4-naphthaquinol-6-T diphosphate in solution at 27 c./mmole is remarkably constant over quite a wide range of activity concentrations (see Table 3).

At −196° C the proportion of free radicals which have sufficient energy for interaction with the solute is expected to be quite small[18] and it is, in fact, observed (Table 3) that the presence of benzyl alcohol as a free radical scavenger has a much less pronounced useful effect at this temperature. This suggests that secondary radiation effects[4], that is, the interaction of the tritiated compound with reactive species (such as free radicals), are almost eliminated at −196° C.

Table 2. Storage of Tritiated Compounds in Aqueous Solution in the Presence of Free Radical Scavengers

Compound	Specific activity (c./mmole)	Activity concn. (mc./ml.)	Scavenger	Age (months)	Storage temp. (°C)	Dose (rads)	$G(-M)$	Decomposition (per cent)

* Values at other temperatures are included for comparison.
† Containing 1 per cent benzyl alcohol.
G equals generally labelled in non-labile positions (ref. 19). The $G(-M)$ values recorded in Tables 2 and 3 are the number of molecules of the tritiated compound destroyed per 100 eV of absorbed energy.

It appears, therefore, that many tritium compounds, preferably dispersed in a solvent, have a much reduced rate of decomposition when stored at −196° C. It is perhaps only inconvenience which prevents a wider use of storage at −196° C.

There is obviously much more information to be obtained concerning even the two aspects of tritium compound decomposition briefly described in this article. Experiments are continuing at the Radiochemical Centre.

I thank Dr. J. R. Catch for his interest, and other colleagues for their assistance.

AN ALTERNATIVE MULTI-TARGET EQUATION USEFUL FOR FITTING SURVIVAL CURVES OF X-RAY IRRADIATED PROTOZOA

By Dr. JOHN CALKINS

Division of Radiobiology, Department of Radiology, University of Kentucky College of Medicine, Lexington, Kentucky

SYSTEMATIC attempts to explain the behaviour of irradiated biological materials have been collected into a group of concepts generally termed 'target theory'. Target theory has undergone constant modification, especially in its objectives; and even though there are objections to the implications of this approach it still provides a logical method and useful vocabulary for a systematic and quantitative investigation of radiation effects. Target theory has been most extensively developed for biological materials which show an exponential decay of activity with dose; this response has been called 'single hit' and implies that some sort of an all-or-nothing event has occurred which either inactivates the material or leaves it completely unharmed. Many biological materials do not show the 'single hit' type of inactivation, but show curves of dose versus activity which have shoulders indicating some damage must accumulate before the full inactivation is expressed; such a response curve is called sigmoidal.

The equation:

$$S = 1 - (1 - e^{-Kx})^N \qquad (1)$$

where S is the surviving fraction, x is the X-ray dose, and K and N are experimentally determined parameters, frequently called the multi-target equation of target theory, has been used as the mathematical model for the sigmoidal type of inactivation of micro-organisms and single cells[1]. This equation can be derived from two assumptions: (1) the inactivation of the targets is a 'single hit' type event; (2) there are N targets each of which must be inactivated to kill the organism. The parameter K is related to the sensitivity of the individual target, being the reciprocal of the mean lethal dose (37 per cent survival dose) for the targets considered individually.

Plots of the observed surviving fraction of various irradiated unicellular biological materials against X-ray dose have almost invariably produced dose–response (survival curves) of the sigmoidal type. In the case of single mammalian cells the observed survival seems to fail to fit the multi-target equation for several reasons. There appears to be a substantial part of the cell population inactivated by the 'single hit' mechanism, that is, N equals 1 for part but not all the population[2]. The 'single hit' component causes the survival at low doses to deviate from values of N and K determined at high doses, and the survival line shows a finite slope as it approaches zero dose instead of the zero slope predicted by the multi-target equation.

The growth phase of cells has also been shown to affect the response of irradiated cells in the cases where it has been investigated[3,4]. It has been shown that a non-homogeneous population could produce quite complex survival curves, depending on the composition of the population and the manner in which the dose–response curve varied in the various subcomponents of the population. When a population of mammalian cells, synchronized with respect to phase in the growth-cycle, was investigated for radiation response, it was found that the response at lower doses seemed sigmoidal with a slope depending on phase in the growth-cycle, but at higher doses a steeper decline of survival might occur.

Survival curves of Protozoa do not show the same deviations from the simple multi-target behaviour that mammalian cells show[5]. If there is a component of the population which is inactivated by 'single hit' kinetics, which would cause the survival curve to approach zero dose with a finite slope rather than zero slope, it must be an exceedingly small fraction. In the case of Protozoa the surviving fraction is 1·0 until quite large doses have been delivered, then a small increase in dose produces a large drop in survival.

The problems originating in the variation in sensitivity during the growth-cycle also seem to be minimal in Protozoa. The sharpness of the threshold would be impossible if there were large differences in the radiation response during the growth-cycle. In the case of *Paramecium aurelia* it has been shown, using animals synchronized by selection in the process of division, that the variations in radiation sensitivity during the growth-cycle are much less than the corresponding variations in mammalian cells, and the data are compatible with the hypothesis that there is no variation in radiation sensitivity during the growth-cycle[6].

Table 1

Eq. No.	Exp. No.	LD_{50}	N	K	χ^2	DF
1	26	6·43	275	0·93	7·33	4
2	26	6·56	9·12	0·06	4·83	4
1	27	7·66	255	0·77	5·35	4
2	27	7·7	27·9	0·06	3·96	4
1	28	6·97	1,544	1·1	2·98	4
2	28	7·1	56·6	0·09	1·62	4
1	29	Computer programme failed to converge				
2	29	6·65	126	0·09	1·59	3
1	30	6·34	10·7	0·44	1·01	4
2	30	6·65	1·83	0·03	0·88	4
1	31	6·79	565	0·99	1·88	4
2	31	6·87	15·9	0·07	1·62	4
1	32	6·19	2,035	1·29	1·31	3
2	32	6·26	67·02	0·12	1·14	3

Survival curve parameters as determined by the two equations. The dose units for the LD_{50} and parameter K are expressed in minutes at 45 krads/min.

Fig. 1 (dotted curve) and Table 1 present experimental data from a number of X-ray survival experiments on *Paramecium aurelia* and illustrate the ability of equation (1) to serve as a model for the inactivation of this protozoan. The data have been fitted using an electronic computer, IBM type 7040; the programme is an iterative type kindly prepared by Dr. Alan Ross and Mr. Stuart Riley of this institution. The values of χ^2 in the separate cases suggest that, within the limitations of the experimental data, equation (1) closely approximates the functional dose–response relation.

There are, however, reasons for seeking a different mathematical model to describe the dose–response relation for X-ray irradiated *Paramecium aurelia*. There is no easy technique for determining the survival of *Paramecium* at extremely low levels as there are for bacteria or tissue culture cells, so survival curves are seldom extended to surviving fractions below 10^{-3}. However, theoretical curves, computed from equation (1), best fitting the data at higher levels of survival, consistently overestimate the survival at the highest dose points instead of a random distribution about observed points at the higher dose-levels. Another reason for further consideration of the model equation is the extremely high values of N. It is difficult to imagine a cellular structure duplicated

thousands or tens of thousands of times, which, if only one N is undamaged, will permit the survival of the animal. The theoretical curves could be made to fit the points of low survival better by increasing the parameter N, but the foregoing objection would be intensified.

Neither objection can be regarded as sufficient reason to discard a model which fits the experimental data to the degree indicated by the χ^2 values; however, a slight modification of equation (1) produces an improved fit of the experimental data and considerably mitigates the two objections already cited.

Equation (1) has been modified in such a manner that the dose appears raised to the second power:

$$S = 1 - (1 - e^{-Kx^2})^N \qquad (2)$$

The symbols have the same meaning as before.

Table 1 illustrates the fact that equation (2) gives an improved fit to the data points and Fig. 1 shows that, although there is still a tendency to overestimate the survival at higher doses, equation (2) is close to the observed values. Table 1 also shows that the parameter N, although still a substantial number, is much less than the value found using equation (1). *Paramecium*, it should be noted, has a complex nuclear organization and a particular bit of genetic information might be duplicated up to 100 times.

Calkins has already reported[7] and Figs. 2 and 3 show another X-ray response of *Paramecium aurelia* in which the functional relation between exposure and response is of such a nature that it is the square of the dose which is significant. Fig. 2 shows the average growth of *Paramecium* following irradiation; since non-surviving animals die without division, the growth is determined entirely by survivors of the various doses. It is evident that there is a progressive depression of the resumption of growth by the increasing radiation doses. An electronic computer programme has been used to determine the delay of growth of the isolated irradiated individuals. Fig. 3 shows the average delay of growth of animals given various irradiation doses and the standard error of this delay plotted as a function of the square of the X-ray dose. The dose-squared dependence shown in Fig. 3 has been repeated in many other experiments.

The dependence of an effect on the square of the absorbed dose could originate in many different ways. One manner of producing such a functional relation could be an interaction between two radiation-produced events which are themselves linearly dependent on dose; the dose-squared relation between effect and dose of ionizing radiation is well known in certain types of chromosome aberrations and seems logically explained by the interaction of effects which show a linear dependence on dose[8].

If the correct functional relations between dose and response can be established for this animal then they will undoubtedly suggest further avenues of investigation in the effort to understand the complex and often bewildering manner in which irradiated organisms behave.

NEAR ULTRA-VIOLET SPECTRUM OF WHITE POTATO MITOCHONDRIA

By Dr. MATTHEW A. HARMEY, Dr. HIROSHI IKUMA and Prof. WALTER D. BONNER
Johnson Research Foundation, University of Pennsylvania, Philadelphia

CHANCE *et al.*[1,2] and Holton[3] observed a broad absorption peak at 315–320 mμ in the difference spectrum of animal mitochondria. This peak has been attributed to bound pyridine nucleotide[1,3] or to a modified form of ubiquinone[2]. During investigations of plant mitochondria, the presence of a similar peak has been detected in mitochondria isolated from white potato tuber, Jerusalem artichoke tuber and mung bean hypocotyls. This article concerns the characterization of this absorption peak in white potato mitochondria.

Mitochondria were prepared as described[4] and tested in a reaction medium consisting of 0·3 M mannitol, 10 mM phosphate buffer (*p*H 7·2), 10 mM potassium chloride and 5 mM magnesium chloride. All experiments described herein were performed with succinate as substrate.

In a difference spectrum of these mitochondria, anaerobic minus aerobic steady states (Fig. 1), an absorption peak is found at 315 mμ, and a shoulder at 340 mμ. The shoulder can be attributed to intramitochondrial pyridine nucleotide; extraction of these mitochondria showed a total pyridine nucleotide content (NAD + NADH) of 5·0 mμmoles/mg mitochondrial nitrogen. In agreement with published reports[5] neither NADP nor NADPH was present in detectable amounts.

Fig. 2 shows a series of experiments carried out to examine the participation of the 315 mμ compound in oxidative phosphorylation. Fig. 2*A* shows the pattern of oxygen uptake detected polarographically. The respiration is stimulated by ADP (state 3) and the rate decreased on exhaustion of added ADP (state 4), showing that the mitochondria have respiratory control[6]. Fig. 2*B* is a fluorescence trace obtained with an Eppendorf fluorometer[7]. Fluorescence is low during state 3. It increases in state 4 and decreases at anaerobiosis (state 5), suggesting that some quenching occurs as soon as anaerobiosis sets in. Figs. 2*C–E* illustrate typical traces obtained with an ultra-violet double-beam spectrophotometer[8] using 305, 320 and 350 mμ as measuring beams with 375 as reference wave-length. In later experiments 300 was used in preference to 305 as a measuring beam. The absorption changes at 350 are typical of energy-linked pyridine nucleotide reduction[9,10], while at 305 mμ the absorption gradually increases on addition of ADP, and on exhaustion of added ADP a first-order decrease of absorption occurs. It should be noted that no steady state was observed during state 3 or 4 or this wave-length. On anaerobiosis, however, the absorption increases to a steady level. The optical changes at 320 mμ are clearly intermediate between those at 305 and 350 mμ.

The results with the double-beam spectrophotometer suggested that it was possible to separate and define more clearly the two components suggested in Fig. 1. Measurements were therefore made over the 290–360 mμ range of wave-length. The degrees of optical changes after ADP addition were determined with reference to the time of ADP addition. At shorter wave-lengths this was determined by extrapolation. Fig. 3 shows the results where the rate of absorption increase immediately after ADP addition is also plotted. The spectrum for anaerobiosis is essentially the same as that shown in Fig. 1. While the 340 mμ absorbing compound is distinguished in the spectrum for state 4 (curve *B*), the 300 mμ species is clearly separated both in the spectrum for the rate of absorption increase and in the plot for the time of ADP exhaustion (curve *A*). These results demonstrate that the 315 mμ peak and the 340 mμ shoulder observed in Fig. 1 are resolved into 300 and 340 mμ absorbing components. The selection of 300 and 350 mμ in Fig. 2 was made to minimize overlap of the two components. In view of the evidence presented, the 315 mμ peak in Fig. 1 can be attributed to the simultaneous absorption of 300 and 340 mμ components at anaerobiosis.

In view of the fact that ADP increases absorption of the 300 mμ component and that the absorption decreases on

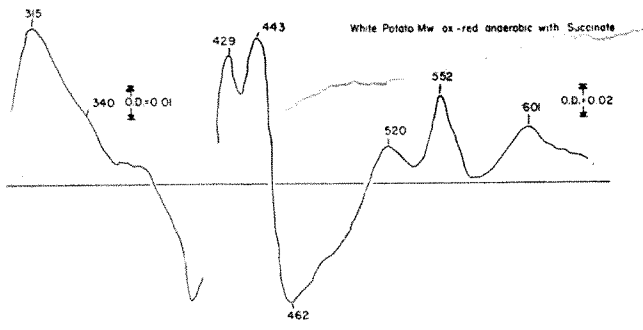

Fig. 1. Difference spectra, anaerobic steady state minus aerobic steady state

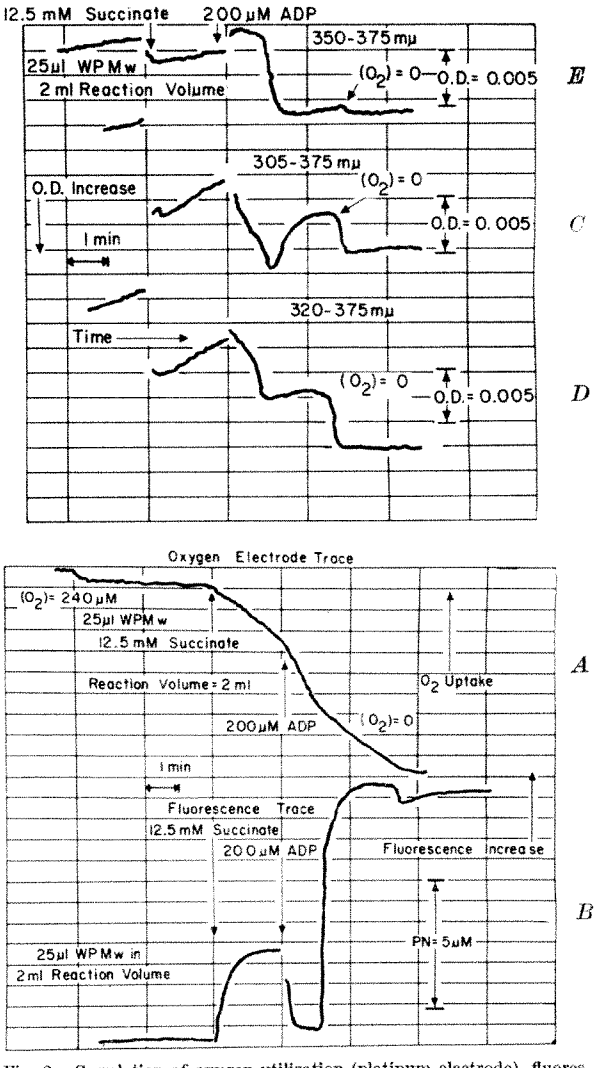

Fig. 2. Correlation of oxygen utilization (platinum electrode), fluorescence, and ultra-violet absorbing species in oxidative phosphorylation

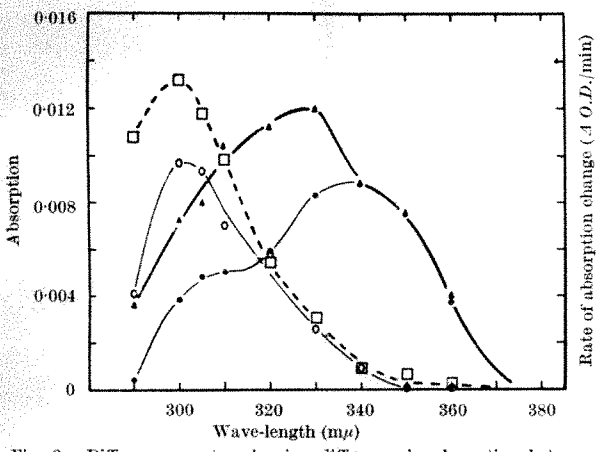

Fig. 3. Difference spectra showing difference in absorption between immediately after ADP addition and (*A*,—○—) at the end of state 3, (*B*,—●—) at the end of first-order change, or (*C*,—▲—) at anaerobiosis. (*D*,- -□- -), the rate of absorption change after ADP addition. Timing and addition sequence were the same as in Fig. 2 for all the runs

ADP exhaustion, two questions arise: (*a*) Does the ATP formed during state 3 inhibit the increase in absorption at 300 mμ ? (*b*) Does the presence of ADP inhibit the first-order decrease of absorption ? Fig. 4 shows the results of an experiment designed to answer these questions. Treatment of the mitochondria with ATP brings about the first-order decrease of absorption after succinate addition, and the kinetics of increase and subsequent decrease of absorption on ADP addition is essentially the same in the presence of ATP as in the absence of added ATP. A further examination of the questions was made by adding excess ADP to bring state 5 directly from state 3. In the presence of excess ADP, the first-order decrease does not occur while the increase in absorption is not affected. One may conclude, therefore, that the ATP formed in state 3 does not interfere with the appearance of the 300-mμ component and both the exhaustion of ADP and the presence of ATP are the necessary conditions to bring about the first-order change of absorption. Fig. 4*C* points out, furthermore, that the ATP-dependent decrease of absorption is indeed an oxygen-dependent process. This latter point is confirmed by the observation that addition of ATP in state 5 did not cause any first-order change.

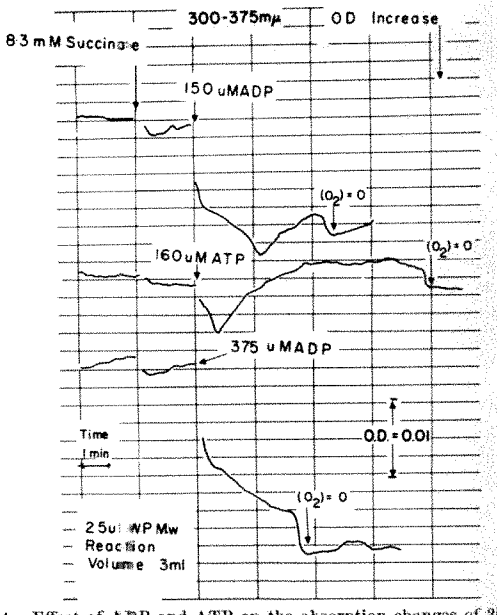

Fig. 4. Effect of ADP and ATP on the absorption changes of 300 mμ compound. Measurements taken with ultra-violet double-beam spectrophotometer. *O.D.* increase, downward deflexion

In conclusion, the 300 component behaves in a manner similar to a respiratory pigment; the response to ADP and oxygen suggest that it is involved in oxidative phosphorylation. The kinetics of oxidation and reduction of the 300 mμ component distinguish it from pyridine nucleotide and ubiquinone. The exact nature of this component is at present not known.

REFLECTIVITY OF ATMOSPHERIC SHOCK WAVES

By WILLIAM R. MALLORY
Electronics Laboratory, General Electric Company, Syracuse, New York

A SHOCK front is a thin layer which separates two regions of different density in the propagating medium. Light incident on such a region will be partially reflected in accordance with Fresnel theory: the percentage reflected is related to the change in density and to the thickness of the transition region. The reflectivity of shock fronts has been studied theoretically by Cowan and Hornig[1], who also made experimental measurements which substantiated the theory. The theory predicts reflectivities of the order of 10^{-7} with shock waves of mach 5 or greater propagating in gases at normal temperature and pressure. For lower mach numbers the thickness of shock front becomes of the order of the optical wave-length and the reflexion coefficient falls exponentially. The reflexion is specular.

During laser ranging experiments at our laboratory, reflexions have been observed from locally turbulent regions in the atmosphere. It has been shown that Fresnel reflexions are not large enough to explain such observations[2]. Since it was very unlikely that the density variations in the turbulence observed were either as abrupt or as large as those which would be found at a shock front, it was felt that the reflectivity of atmospheric shock fronts might be higher than predicted by the theory. Therefore, tests on a shock wave propagating in the atmosphere were made. The tests yielded surprisingly high values of reflectivity, of the order of 5×10^{-3}, from the region of the shock front.

Experimental Determination of the Reflectivity of a Shock Front

The method used in the experiment was to measure with a laser range-finder[3] the range first to an explosive charge and second to a shock front propagating from the charge, while simultaneously monitoring both the transmitted energy and the reflected energy on a wide-bandwidth dual-beam oscilloscope. In the second measurement, the firing of the laser range-finder was delayed until after the detonation in order to allow the shock front time to propagate ahead of the fireball produced by the

explosion. High-speed shadowgraphic cinephotographs[4] were taken of the explosion to confirm that the reflexions measured were from the shock front region, and not from the fireball or extraneous matter present.

A photograph of the laser range-finder is shown in Fig. 1. The transmitter is a *Q*-switched ruby laser with an output wavelength of 6943 Å, a peak power of about 5×10^5 W, an output beam divergence angle of about 0·5 milliradian, and a pulse length of 30 nsec. The ranging accuracy is ±1 ft. To discriminate against the noise from the fireball and/or shock wave, a tuned multiple dielectric filter having a full-width-at-half-power of 5 Å and a peak transmission of 0·4 was used in the receiving optics. The receiver was gated by an S.T.C. circuit so that the receiver did not saturate from the optical noise power transmitted through the filter.

The explosive was suspended at a height of 10–15 ft. above ground. The detonator cap and all lines and cables were placed in such a position that none of them was blown forward by the explosion. The charge was 1–10 pounds of composition *C*, which yielded shock waves in the range of mach 1·25 to mach 1·6. The separation of the laser range-finder and the suspended charge was about 470 ft.

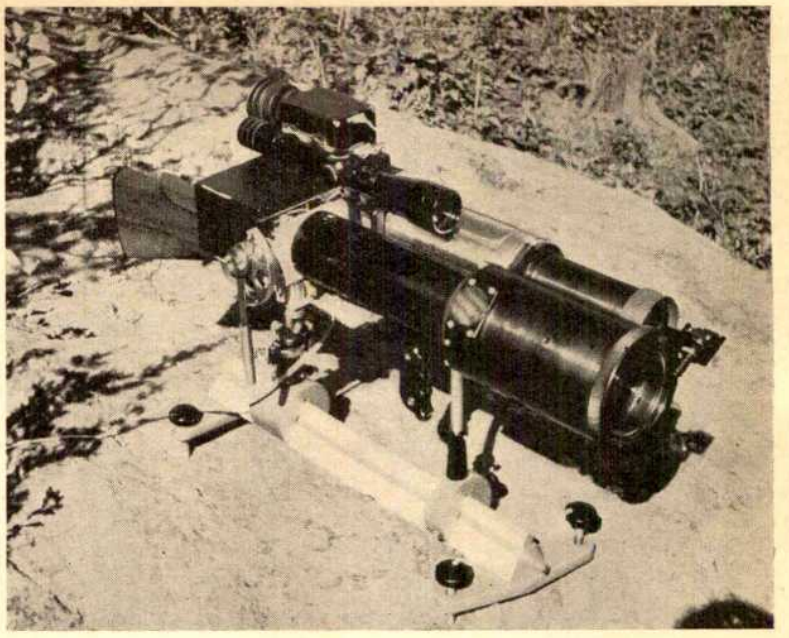

Fig. 1. Laser ranger

The experimental procedure begins with the start of the drive mechanism of the 'Fastax' camera. After the camera drive attains the proper speed, the charge is detonated and, after a delay of 1–4 msec, the laser range-finder is fired. Timing signals are recorded on one channel of the oscilloscope at the time the charge detonates and also when the laser fires. The detonation signals are obtained by means of a piezoelectric barium titanate disk buried in the charge. The laser transmitter emits a single pulse toward the approaching shock wave. A fixed fraction of the energy in the transmitted pulse is coupled directly into the receiver. This pulse starts the range counter and the second oscilloscope trace. When a reflected signal is received the counter is stopped. In addition, the output from the receiver is displayed on the second trace of the oscilloscope. The oscilloscope display generated prior to detonation is generated in exactly the same manner, except that the detonator is disconnected and the reflexion occurs from the suspended charge.

The range counter on the laser range-finder was used to determine differences in the range—this counter having a resolution of 1 ft. The scope traces were used to estimate the reflectivity of the shock front. The reflectivity values were estimated by comparing the signal reflected by the shock front with that reflected from the suspended charge prior to detonating. To make certain that variation in output power of the laser did not affect the results, both reflected signals were normalized by sampling the transmitted beam. It was necessary to estimate in some cases what portion of the laser beam was intercepted by the charge. This estimate was rather rough (within a factor of 2 or 3), so the values of reflectivity should only be treated as correct in order of magnitude.

Fig. 2 shows a portion of a typical film from the 'Fastax' camera. The frame rate was 3,750 frames per sec. The flash in the second frame indicates initiation of the explosion (the figure is a negative, so the flash appears as a darkening). The oscilloscope data give the delay times between detonation and ranging with the laser range-finder. It can, therefore, be determined which frame of the film (±1 frame) in Fig. 2 shows the positions of the shock front and fireball at the time of ranging.

In Fig. 2, the lower series of frames is a continuation of the upper with time increasing from left to right in both cases. The dark rectangular area is a 'Scotchlight' screen[4] mounted opposite the camera. The shock wave appears in Fig. 2 as a thin bright band travelling across the screen. In the frame at the left end in the lower series, the shock front is a horizontal line at the centre of the screen in line with the longest marker (a white strip also). In the following frame the shock front has moved upward a short distance. (The upward direction in Fig. 2 corresponds to the direction toward the laser range-finder.) The fireball appears in Fig. 2 as a dark mass at the bottom of each frame. The separation (along the laser line-of-sight) of suspended charge, shock front, and the foremost edge of the fireball could be determined by projecting distances scaled from Fig. 2 on to the laser line of sight.

Complementary data from the range counter, the oscilloscope record, and the high-speed film are available from four shots. These data are shown in Table 1. It should be noted that the separation between the shock front and the fireball was between 2·5 ft. and 5·5 ft. These distances are sufficient to ensure that the ranges obtained were actually occurring from the shock front and not from the fireball or from solid matter.

Assuming the explosive to have a (diffuse) reflectivity of 0·1, values of (diffuse) reflectivity for the shock front were calculated. The values obtained varied between 0·003 and 0·01 with a mean of 0·0065.

On one shot the laser was aimed below the charge during the explosion so that the laser beam was incident at an angle of about 0·3 radians—much greater than the transmitter beam divergence of about 0·5 milliradians. Within the limited accuracy of the reflectivity estimates, there is no reduction in reflectivity for this shot. Thus, the reflecting mechanism is not specular.

The experiment demonstrates that optical reflexions from shock fronts produced by explosions in the atmo-

Table 1

4	9	7·5	10·5

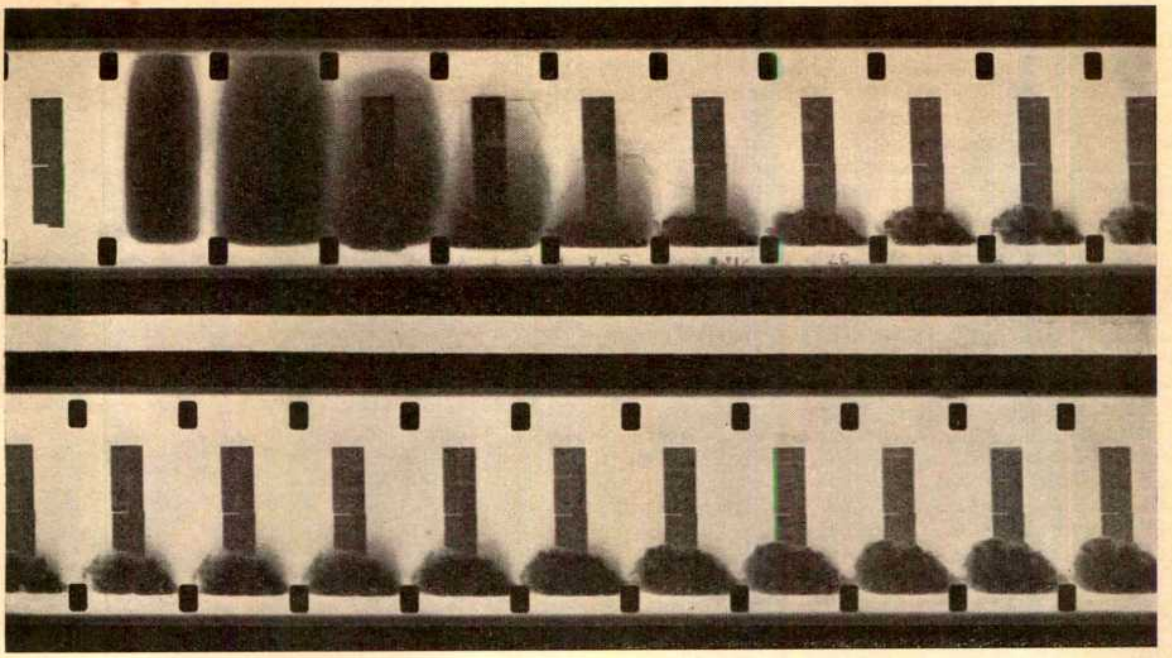

Fig. 2. Film strip from 'Fastax' photographs of the explosion

sphere can occur which are much larger than would be expected on the basis of Fresnel reflexions. The reflexions also appear to be non-specular.

The most likely explanation for the anomalously high reflectivity observed is that water droplets are condensed. This is suggested by the fact that previous results with (presumably) dry gases in shock tubes were adequately explained as Fresnel reflexions. The mechanism for any such condensation is not obvious. Other possibilities are: (1) that particles are swept along with the shock front, (2) that reflexions occur from an ionized plasma. The fact that the light source used in the experiment is much more coherent than those used in previous work may also need to be considered.

Investigations are being carried out to decide which, if any, of these explanations is the correct one.

BORON CONTENT IN RELATION TO ORGANIC CARBON AND TO PALAEOSALINITY IN CERTAIN BRITISH UPPER CARBONIFEROUS SEDIMENTS

By Dr. R. M. C. EAGAR
The Manchester Museum, University of Manchester

AND

Dr. D. A. SPEARS
Department of Geology, University of Sheffield

In sedimentary rocks the presence of fossil species of groups of life now characteristic of exclusively marine environments, such as brachiopods, cephalopods and certain families of lamellibranchs, indicate past marine conditions. Furthermore we have good reason, at least by Carboniferous times, to postulate that salinities were no different from those of seas to-day[1]. In the Upper Carboniferous, members of some other fossil groups, on the evidence of their association and relative position in short sequences of changing facies, appear to have ranged from marine to brackish water. Yet others, by the same kind of criteria, evidently characterized brackish water environments and may have ranged into fresh water[2]. The latter include the 'mussels' of the Coal Measures, lamellibranchs of the extinct Family Anthracosiidae and some members of the Myalinidae. These lamellibranchs, which have left prolific accumulations of shells at many horizons, have been cautiously described as non-marine. We can be sure only of the fact that palaeosalinities were in general lower in Carboniferous times during the prevalence of non-marine conditions, as is evidenced by life assemblages of 'mussels', than during the deposition of bands with marine fossils.

In attempts to find other independent criteria to differentiate marine sediments of all ages from those of lower salinity, including fresh water, much recent work has been directed towards the quantitative determination of minor elements, especially boron[3]. The use of total boron content and boron in illite[4] as indicators of palaeosalinity in British Upper Carboniferous rocks has been questioned independently by both of us[5,6]. For example, from an investigation of a sequence of fine-grained shales and shaly mudstones with non-marine faunas in the Lower Coal Measures of Worsborough, Yorkshire, Eagar concluded that evidence from total boron contents of 21 samples was at variance with all other evidence regarding palaeosalinity. In this investigation, however, the most striking relationship appeared to be an antipathetic one between total boron and organic carbon, the latter representing original organic matter in the sediments. The relation-

ship, it was concluded, might be direct or indirect. The possibility of there being a direct relationship between these elements was later noted by Curtis[7,8] from work on a slightly higher horizon in Yorkshire. Curtis directed attention to Bader's demonstration[9] that certain clay minerals, including illite, will quickly and strongly absorb up to 350 per cent of their own mass of soluble organic matter from solution; he pointed out that this same mechanism could inhibit boron sorption in the natural environment.

The purpose of this article is to supplement published data from the Worsborough section with checks on total boron contents and with determinations of the potassium contents of the samples, work carried out by Spears. These results are presented in order to investigate the nature of the carbon–boron relationship and its bearing on boron as a supposed index of palaeosalinity, not only at Worsborough but also in certain other Carboniferous successions.

Boron contents of the samples in the Worsborough section were originally determined by a microchemical technique in the laboratories of the North Rhine–Westphalian Geological Survey of Krefeld[10]. Ernst later pointed out that these figures were too high as a result of an error in standardization later discovered[11], but that the carbon–boron relationship was not affected by the revised figures[12]. A plot of the spectrographic results gives essentially the same graph as that produced by Eagar[5] from microchemical results. There is one difference, however, in that all organic carbon peaks now correspond precisely with boron troughs (Table 1), whereas in the first plot, when microchemical determinations were used, it was noted that in the case of three organic carbon peaks out of six the fall in boron slightly preceded the rise in organic carbon.

In the earlier work on Worsborough no potassium figures were available. The new analytical data have been plotted on Fig. 1, from which it will be seen that although samples with a high content of organic carbon have low boron values, potassium figures are also much lowered. The correlation between boron and potassium is good ($r = +0{\cdot}93$). The best fitted line, however, is the quadratic curve $y = 12{\cdot}71x - 5{\cdot}65x^2 - 2{\cdot}56$, where x represents boron in p.p.m. and y is the percentage of potassium oxide. The expression approximates to a straight line for the greater part of the recorded data but gives proportionately higher boron values when potassium oxide is very low and very high. There is some scatter of points about the lines on Fig. 1, which must be regarded as inevitable, but it is more convenient to discuss its possible causes later in the article when Fig. 3 is described.

Samples from the measures above the Flockton Thin Coal at Cold Bath Opencast, Worsborough, near Barnsley, Yorkshire. Determinations of organic carbon, sulphur and free silica by A. Parr-Burman and G. Y. Gillespie, United Analysts, Ltd., East Boldon; K_2O and boron by D. A. Spears. The samples at 61 ft. 6 in. and 3 ft. 2 in. above the coal are additional to those used by Eagar (ref. 5), Fig. 1. Dark organic-rich bands are numbered.

* Boron content average of triplicate determinations. Average coefficient of variation is 6·5 per cent.

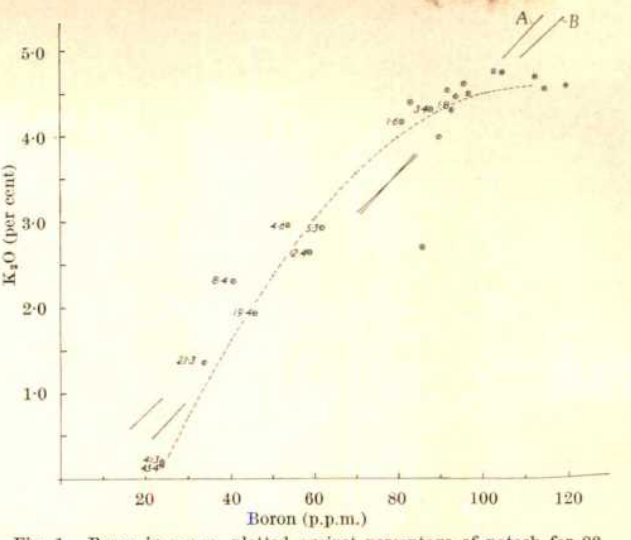

Fig. 1. Boron in p.p.m. plotted against percentage of potash for 23 samples of shales and shaly mudstones from the succession above the Flockton Thin Coal at Coal Bath Opencast, Worsborough, near Barnsley. Figures for organic carbon are inserted when they reach more than 1·5 per cent. Boron and potash determinations by D. A. Spears; organic carbon by A. Parr-Burman, United Analysts, Ltd., East Boldon. The curve which provides the best line for the data has been computed by S. M. Ali of the Statistical Laboratory, University of Manchester. *A*, B on K_2O; *B*, K_2O on B

We consider first the approximately linear relationship. If most of the boron and potassium is contained in the clay mineral illite[13], as seems reasonable from the evidence of numerous analogous investigations[3], then the sympathetic behaviour of these two elements appears to reflect merely abundance of illite. Samples with a relatively low content of both boron and potassium have high contents of organic materials. For these Worsborough sediments the organic material, which at a first approximation may be considered to contain negligible quantities of both boron and potassium, has simply acted as a diluent together with associated carbonates.

Boron and potassium are, however, both essential to biological growth and are known to be concentrated in many plants and animals. Therefore, it becomes of importance, in testing this hypothesis, to assess evidence bearing on the relative magnitudes of contributions to these elements made by clay minerals on one hand and organic matter on the other. Whenever cellular structure has permitted identification, organic carbon in British Coal Measures has proved to be almost exclusively derived from coal-forming land plants. By analogy with the conclusions of Breger and Brown[14], who investigated richly carbonaceous shales of late Devonian age in the eastern United States, and of Tourtelot[15], who worked on late Cretaceous sediments of the same country, the total organic fraction of both marine and non-marine sediments is also likely to be predominantly of the remains of land plants. This conclusion applies especially to samples with very high organic contents. Potassium may reach more than 3 per cent of the dry weight of fresh material from living land plants[16], but reductions in the content of potash have been found in vegetable litter[17] and a further decrease is apparent in humus. In raised bog peat, for example, proportions of potassium in dry matter are of the order of 0·05 per cent or less and concentration of this element in peat waters is correspondingly increased[18]. It is clear, therefore, that in carbonaceous shales the contribution of potassium from plant matter can probably be neglected, but that beds of swamp peat, the original material of Carboniferous and many other coals, might initially hold appreciable quantities[19]. Many living land plants, however, have boron concentrated in their leaves and whole-plant analyses range from 10 to more than 90 p.p.m. in different species[20]. These figures are of magnitudes comparable with those of vitrains in Tertiary[21] and

Carboniferous coals, including British seams. Six British vitrains, analysed 15–16 years ago[22], varied in their boron contents mainly between 2·5 and 8 p.p.m., but ranged up to 70 p.p.m. More recently Roga[23], working on Polish coals, after removing extrinsic boron compounds by density separation, found the remainder to be strongly associated with the vitrain in amounts ranging from 66 p.p.m. in lignites, through 19 to 1·6 p.p.m. in bituminous coals, ultimately to 1 p.p.m. in anthracites. It therefore appears that except in the richly carbonaceous shales of Worsborough (organic carbon more than 15 per cent) the contribution of boron from organic matter can be neglected—a conclusion in agreement with that of Tourtelot[24]. We must, therefore, conclude that for most of the range of the samples at Worsborough the antipathetic relationship noted between total boron and organic carbon contents results primarily from organic carbon acting as a diluent.

From the same survey, however, it is clear that boron in organic matter of plant origin might be expected to make a small but fairly rapidly increasing contribution to total boron as organic carbon increases to more than 15 per cent and as, at the same time, through a diluent effect, the clay mineral content of the sample decreases. An organic source of boron might, therefore, be a contributory cause of the very high ratios of B/K_2O observable in the samples at the base of the section at Worsborough, almost immediately overlying the Flockton Thin Coal (Table 1). On the other hand, the low potassium contents of these specimens could be due to the presence of an illite which has become highly degraded, the increased boron/potassium ratio being the result of the greater stability of boron in the illite lattice. It might also be argued that in these circumstances appreciable boron might be contributed by minerals other than illite. However, such minerals have not been detected. Moreover, an unsuccessful search for tourmaline was made by Spears[6] in comparable Coal Measure sediments, a result in support of the conclusions of Kneuper[25]. On this basis we consider the presence of significant amounts of tourmaline in the Worsborough sediments most unlikely. Both Walker and Price[26] and Spears[6] have noted a tendency for the boron/potassium ratio to increase as the potassium decreases in other sediments in the Carboniferous. The same phenomenon may possibly be connected with the very high B/K_2O ratios of the basal sediments at Worsborough, but if the remaining samples are plotted with these no significant or suggestive relationship between total boron and boron/potassium ratios is revealed. The final possibility, that these high ratios indicate greatly increased sorption of boron by illite, is better discussed after consideration of the significance of the curvature of the fitted line in Fig. 1 and of the data in Fig. 2, in which the increase in B/K_2O ratios at high levels of organic carbon is more clearly seen. There is a suggestion of a continuous series of points between medium-rich to extremely rich carbonaceous shales. Those samples with an organic carbon content of more than 40 per cent consist of cannelly shales little removed from high-ash low-carbon cannel and bituminous coals. If the increase in the boron/potassium ratio in this direction is due to an increasing contribution of boron from organic material of plant origin, or perhaps more strictly to an increasing B/K_2O ratio for the organic constituents of the sediments, then we might expect to find a series of points which continue into the realm of coals. Data from British coals appear to be lacking, but from the very detailed work of Headlee and others on sections within West Virginian coals[19] it seems clear that B/K_2O ratios for coal seams may reach 70 or more in the centres of seams, but that in general they decline towards the margins, so that values of 18–4 occur at the extreme tops of seams and in the richly carbonaceous roof shales. These values are entirely of the right order of magnitude to support our very tentative suggestion of continuity in boron/potassium ratios between carbonaceous sediments and coals. The view is further supported by a consideration of the theoretical curve drawn in Fig. 2 and discussed in the following paragraphs. Nevertheless, we must stress that regional variations in the boron contents of coals of similar ranks are by now becoming apparent. Moreover, the small amount of evidence at present available from coal surveys suggests that such factors as seam thickness and conditions of accumulation and burial may greatly influence the final boron content of the coal[27].

The statistically significant curvature of the fitted line in Fig. 1 is also of interest where organic carbon figures are lower; it suggests that the diluent effect alone is insufficient to explain the considerable decreases in the total boron contents of the dark shale bands. This fact may be simply tested in examples with 10–4 per cent organic carbon by comparing percentage decreases of total boron with those of illite as measured by potash determinations. The slightly larger percentage decreases of the total boron contents seems to imply that less boron was sorbed by the illite under conditions where organic matter was abundant. The B/K_2O ratios of samples having less than 10 per cent organic carbon, in fact, show an inverse correlation with carbon (Fig. 2, where $r = -0{\cdot}45$, a figure which is marginally significant at the 95 per cent level). Since we have concluded that the total boron content of these samples is not appreciably more than that of the clay minerals (essentially the illite content) and since the total potash content (reflecting illite) does not show any significant relationship with the B/K_2O ratio (boron in illite), then it seems likely that boron in illite bears a direct relationship with organic carbon in this range of the Worsborough sediments. If the increase in B/K_2O ratio with decreasing organic carbon reflects a small increase in the sorption of boron by illite, as we might reasonably suppose, then the relationship with organic carbon might perhaps have arisen through the inhibiting action of the original fraction of soluble organic matter in the water, a mechanism to which we have already made reference.

The configuration of the plotted points in Fig. 2 may be considered in the light of a model based on our present knowledge of the sources of boron and organic carbon in sediments and on certain assumptions which we can make about conditions of deposition during the formation of the Worsborough beds. Organic carbon (C, below) can be considered as composed originally of a detrital fraction, the debris of land plants and a soluble fraction, organic molecules in solution. Where organic carbon is high the detrital fraction will obviously predominate, whereas when the total organic carbon content is low the soluble fraction may well have been appreciable. The ultimate boron content of the illite must consist of the sum of the inherited boron (B_1, below) and the boron extracted from solution

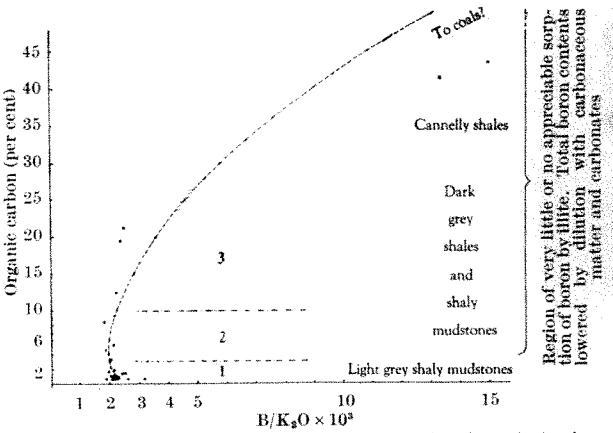

Fig. 2. Percentages of organic carbon plotted against boron/potassium ratios for 23 samples from Worsborough. The curve (see the text, equation (3)) has been computed by R. M. C. Eagar. 1, Region of small amount of boron sorption by illite; 2, total boron content mainly 'inherited' in the illite; 3, total boron content mainly 'inherited' in the illite, but with an increasing proportion of boron contributed by carbonaceous matter (land plants) as the total organic content of the samples increases

near and at the site of sedimentation (B_2, below). There is no reason to suppose any alteration in the source of the sediments deposited at Worsborough, so that we may presume that the inherited or detrital fraction of the boron has remained constant or approximately so. Let us assume also, for the moment, that palaeosalinity changes have been inappreciable, so that sorbed boron is also proportional to potash. Plant debris provides the third source of boron (B_3) and has already been discussed. We may regard B_3 as being a constant but very small fraction of vegetable debris, appreciable only in richly carbonaceous samples.

We have then:

$$\text{B (total boron)} = B_1 + B_2 + B_3 \qquad (1)$$

where

$$B_1 = a\ K_2O,$$

$$B_2 = \frac{b\ K_2O}{C}$$

$$B_3 = c\ C$$

and a, b and c are constants.

Substituting in equation (1) we have

$$B = a\ K_2O + \frac{b\ K_2O}{C} + c\ C \qquad (2)$$

We have noted, however, that K_2O is roughly inversely proportional to C through a dilution effect, so that $K_2O = d/C$ (as may be demonstrated by plotting).

Dividing equation (2) by K_2O and then substituting for K_2O in the third term we have

$$\frac{B}{K_2O} = a + \frac{b}{C} + e\ C^2 \qquad (3)$$

when the constant $e = \frac{c}{d}$

The curve of equation (3) has been plotted in Fig. 2 with the values of the constants determined by trial and error as $a = 1{\cdot}75$, $b = 0{\cdot}547$ and $e = 0{\cdot}0045$. It will be seen that the plotted path provides a good fit for the available data. The equation will account for the very high B/K_2O ratios when organic carbon contents of the samples approach those of low-grade coals and as the contents of potash are greatly reduced through diluency. It will further account for the broad minimum of these values in medium-rich carbonaceous shales, and finally for the small apparent increase in B/K_2O ratios which occurs at low levels of organic carbon and which may indicate appreciable sorption of boron from brackish water by illite under these conditions. We may, therefore, adduce a little more contributory evidence in support of our tentative hypothesis set out in Fig. 2. On the other hand, we do not know whether the presumably slower rates of sedimentation which prevailed during the deposition of most of the darker shale bands (but excluding the band 61 ft. 6 in. above the coal, Table 1) may have introduced other variable factors such as low E_h values which might have affected the result. (G. D. Nicholls has pointed out to us that when organic contents of the sediments were high, low E_h values might have affected the stability of the associated clays. In these conditions the formation of authigenic illite could have been hindered by the production of Fe^{++}-bearing clays, for example, chamositic minerals. Failure or reduction of authigenic illite would have slightly reduced the uptake of boron.) We point out merely that the data of Fig. 2 will at present bear the interpretation that a small amount of boron sorption could have occurred in conditions where soluble organic matter in the palaeo-environment was presumably low and that at medium and high levels of organic carbon, sorption has evidently been less or inappreciable.

Our new data from Worsborough considerably affect the use of boron analyses in the investigation of palaeosalinity in these and similarly constituted sediments. With the assumption that no appreciable boron or potassium is contributed by sources other than the illite, boron/potassium ratios may be multiplied by a constant to arrive at the boron content of the illite, which is the "adjusted boron" of Walker *et al.*[26]. In the case of the Worsborough sediments it will be seen from Table 1 and Fig. 1 that six of the organically rich bands (excluding the basal one, Band 1) have B/K_2O ratios which are no higher than those of the lighter-coloured grey mudstones. The mean boron/potassium ratio for the dark bands, 2·11, is actually lower but insignificantly different from the mean for the grey mudstones, 2·27, although faunal considerations carry the suggestion that the former were laid down under higher palaeosalinities than the latter[5]. The exceptional very high ratios for the two samples from the basal richly carbonaceous band or cannelly shale, overlying the coal, have already been discussed. Although the fauna of all seven dark shale bands are essentially similar, fish scales are more abundant at the lowest horizon, 2 ft. 2 in. above the coal, than elsewhere in the succession. Furthermore, it might possibly be inferred, mainly on geological considerations involved in the cyclic deposition of the Coal Measures, that palaeosalinities could have reached a maximum during the time immediately succeeding the submergence of a coal forest, that is, the peat of the Flockton Thin Coal, and therefore at the time when these beds were being laid down. Nevertheless, we have already produced suggestions and some evidence for two possible contributory causes to these high ratios—degradation of the illite and the presence of appreciable quantities of boron from the debris of land plants when illite contents were extremely low. We should, therefore, be very wary of accepting a third factor—much increased uptake of boron by illite in increased palaeosalinities—when we have already noted geochemical data which could be interpreted as suggestive of a decrease in boron uptake with increasing organic matter; and when, furthermore, we have obtained these results from bands of shale nearly all closely comparable in fauna with the critical bed under discussion. Finally, we note that the increases in boron sorption which must be postulated to account for the observed high ratios are wholly at variance with the model we have developed and seemingly irreconcilable with the available amount of illite as measured by potash analyses. The balance of the evidence is, therefore, most unfavourable to the use both of total boron and boron in, or supposedly in, illite as indicators of palaeosalinity in the Worsborough succession. In so far, however, as changes in palaeosalinity in the Worsborough succession may well have been small, it could be argued that the case is not conclusive. (M. A. Calver, at a meeting of the Yorkshire Geological Society in Leeds (January 18, 1964), when describing the palaeontology of recent cores obtained from the Clay Cross Marine Band in the eastern Pennine Coalfields, about 200 ft. above the Flockton Thin Coal, pointed to several areas in which stunted shells of *Anthracosia*, a non-marine lamellibranch, had been found within the strata of the Marine Band. Shells of this genus on this horizon may lie on the same bedding planes as unquestionable marine fossils. From these recent observations the inference may be tentatively drawn that faunas of *Anthracosia*, the shells of which occur in the carbon-poor sediments of Worsborough, where they are also rather small or stunted, could tolerate an appreciable degree of salinity.)

Further evidence bearing on the issue may fortunately be obtained by comparing the Worsborough analyses with others already published from the Yorkshire Coalfield, where there is evidence of unquestionable marine faunas. In the work of Curtis[3] two sections of the Mansfield Marine Band were investigated. The majority of his 39 samples are characterized by marine fossils, but three come from strata containing non-marine lamellibranchs. Another six results for shales and shaly mudstones yielding non-marine lamellibranchs may be found in the work of Walker and Price[26], so that with the present results from Worsborough the number of analyses for non-marine shales approaches that for marine ones. Since all these samples are located in the same general area of Yorkshire and its

southern border and are of closely comparable geological age they may be compared with some justification (Fig. 3). It will be seen at once that the correlation between boron and potassium for both marine and non-marine shales is again evident, although there is some scatter about the lines. The scatter is to some extent inevitable for several reasons such as experimental error, which is greater for boron than for potassium. Furthermore, illite is thought to be merely the major host for boron and potassium, and, therefore, it is possible that small quantities of these elements do occur independently of one another. The ratio of boron to potassium in illite presumably changes to some extent, because there is no reason to believe that the controls determining the amount of potassium of detrital origin to that of non-detrital origin will be exactly the same for boron. Small amounts of sorbed boron, which we admit may have been proportionately slightly greater in marine than in non-marine conditions, would also add to the dispersion. From a re-examination of Fig. 3 it will be seen that there is no apparent separation of samples into marine and non-marine categories. Although the range of potash contents is greater in the non-marine than in the marine samples and the range of organic carbon very considerably greater, with the result that the regression lines diverge more in the marine samples, the scatter is virtually the same for both. When the fitted lines are calculated by the method of the reduced major axis[29] there proves to be no significant difference in the slopes of the lines, nor is there significant displacement, towards the boron axis, of the marine sample. The means of the boron and potassium contents are greater for the marine than the non-marine samples (92 compared with 78 p.p.m. and 3·96 compared with 3.50 per cent respectively), but the mean B/K_2O ratios, 2·42 for marine and 3·11 for non-marine samples, are not significantly different. The latter results clearly indicate that the differences arise through the presence in the samples of constituents other than illite and by dilution effects, primarily through organic carbon. Statistically the marine and non-marine samples are indistinguishable with respect to their boron and potassium contents. Boron/potassium ratios do not statistically reflect differences in palaeosalinity in these 66 samples from the Yorkshire Coal Measures.

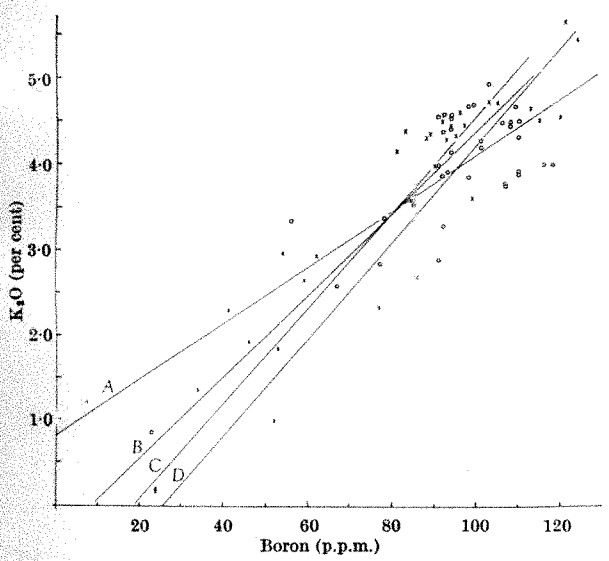

Fig. 3. A comparison of 66 samples from marine and non-marine sediments of the Coal Measures in the areas around Doncaster, Barnsley and Wakefield. Differences in the slopes and displacements of the regression lines are not statistically significant. The reduced major axes, which approximately bisect the angles formed by the regression lines, have been omitted to preserve clarity in the figure. ○, Marine shales: Mansfield Marine Band, Little Smeaton and Bilby boreholes. ×, Non-marine shales: Worsborough (ref. 23), Wakefield Westgate Brickworks (6 from ref. 26), and Little Smeaton borehole (ref. 3). *A*, K_2O on B (marine); *B*, K_2O on B (non-marine); *C*, B on K_2O (non-marine); *D*, B on K_2O (marine)

We therefore conclude that changes in palaeosalinity in the measures with which we are concerned are indicated neither by changes in total boron contents nor in boron/potassium ratios, and that this generalization applies both within single sections and also when averages are taken throughout the samples investigated. We consider that a limited amount of sorption of boron by illite may have occurred both in marine and non-marine conditions, where the water was often brackish, but stress that our evidence indicates that any fraction of boron taken up from solution must have been relatively small. Much the greater part of the boron was evidently carried into the sedimentary area in suspension, as the detrital or inherited fraction in illite, a conclusion which is in agreement with those of Nicholls[30], Hirst[31] and others, including Spears[6].

The antipathetic relationship previously noted by Eagar between total organic carbon and boron contents at Worsborough has proved to be indirect, in so far as it arises from dilution of the samples by other constituents, primarily organic carbon; but we have also found some evidence to suggest a direct inverse relationship between carbon and boron/potassium ratios. This relationship is apparent at levels of organic carbon below 10 per cent and may be connected with a process such as Curtis has suggested in which boron sorption can be inhibited by soluble organic molecules. When the organic carbon contents of the samples are very high (15 per cent or more) we have noted the possibility that an appreciable quantity of boron may be contributed by debris from land plants and boron/potassium ratios of the samples may be raised by this means. B/K_2O ratios may, in fact, form a continuous series increasing in value in samples ranging from carbonaceous shales to low-ash bituminous coals; but this tentative suggestion requires further investigation.

LETTERS TO THE EDITOR

ASTRONOMY

Structure of the Crater Alphonsus

The photographs of the Crater Alphonsus obtained by *Ranger* IX show several features which may have structural significance from the point of view of the history of the lunar crust.

An examination of the northern side of Alphonsus (Fig. 1) indicates a horizontal offset along the central spine. The southern side, being irregular in outline, is more difficult to interpret. The general impression of the overall outline is, however, that the eastern (astronautical) side is displaced toward the south with respect to the western side.

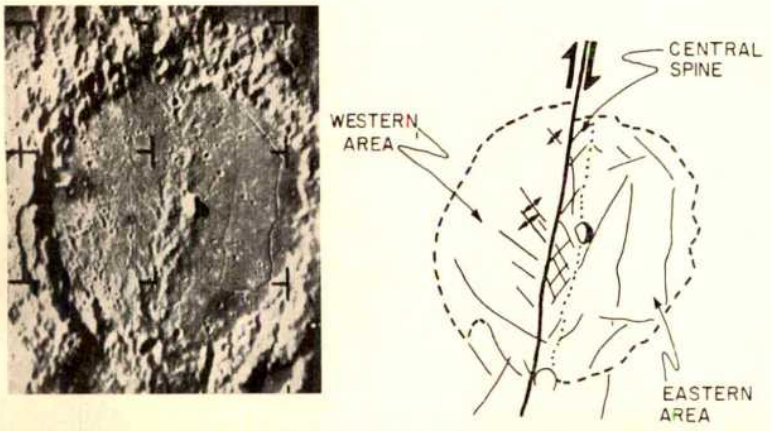

Fig. 1. *Ranger* IX photograph No. 0537 and schematic line drawing. The central spine area separates the western area from the eastern area. The dextral strike-slip fault is indicated by the offset of the northern 'shore' and by the orientation of the folds and lineaments. The central spine and central peak are probably volcanic

The presence of strike-slip faults on the Moon has been a matter of controversy for some time. Fielder[1,2] has described several of them on the basis of outlines, while MacDonald[3] and Baldwin[4] believe that there are no large-scale strike-slip faults. The presence of a strike-slip fault on the floor of Alphonsus is suggested not only by the offset of the northern 'shore', but also by the analysis of the lineament, as will be shown here.

Three areas can be defined on the floor of Alphonsus; the area west of the central spine, the area of the central spine with the central peak, and the area east of the central spine. The movement seems to have occurred on the border between the central spine and the western area, aligned with a lineament that goes from one of the sides of Ptolomaeus to Arzachel.

Three sets of lineaments are present on the floor of the crater: set *A* with azimuth approximately north-east–south-west, set *B* with azimuth approximately north-west–south-east, and set *C* approximately north–south. Few other lineaments of different azimuths are present, and they may be explained by distortions produced by the crater rim. The regularity of some of the lineaments along their extent, especially the rilles, is an indication of an extreme areal homogeneity in the material which constitutes the floor of the crater. Some of the lineaments in the western area, with azimuth of approximately north-west–south-east, appear under careful examination to be folds rather than depressions. Folds have not previously been noticed on the lunar surface.

Although the horizontal displacement could be apparent, rather than real, due to vertical motion of the inclined sides of the crater, the lack of a difference in elevation between the east and west rims and the character of the lineament is more consistent with an offset due to a dextral strike-slip fault. In particular, the fractures and folds oblique to the fault are characteristic of the dragging produced by strike-slip faults on overlying formations[5,6]. This can be easily verified by applying a couple with one's hands to a sheet of paper. The folds, oriented approximately north-west–south-east, match the proposed dextral movement of the strike-slip fault.

Rather than one single fault, it seems likely that a fault zone is present, extending the whole width of the central spine of Alphonsus.

It is possible that the central spine was formed by igneous eruptions which were localized by, and occurred along, the fault zone; and that the central peak could be similar to the famous *aiguille* of Pelée Mountain in Martinique, that is, a peak caused by the slow extrusion of a very viscous magma. The similarity between photographs of Pelée Mountain[7] and the central spine of Alphonsus is striking. The rest of the crater floor could be covered by ignimbritic material, which often accompanies Peléan volcanism. The lineaments on the central spine area indicate that the movement continued during and after the eruptions.

Regardless of the origin of the material forming the central spine and floor of the crater, it would seem from both the general outline of the crater and the presence of the folds that Alphonsus is a crater deformed by a strike-slip fault of dextral type.

I thank the National Aeronautics and Space Administration and the Jet Propulsion Laboratory for providing the *Ranger* photograph, and Dr. J. W. Salisbury for his advice.

GEOPHYSICS

Explosive Phase Transitions in the Earth's Mantle

The Earth's crust and mantle deform viscoelastically. There has, therefore, been some question as to whether stress relaxation rates in the upper mantle and lower crust might not exceed any realistic rates of stress accumulation. If this is so, earthquakes could not be generated by rebound of elastic strain; that is, by either the type I or type II source of Honda[1]. It might, therefore, be worth-

while to explore the possibility of an earthquake mechanism in which stress is suddenly applied rather than suddenly released. One such mechanism is a phase transition, quasi-instantaneous over a finite volume and involving lattice condensation. Recent experiences with underground nuclear explosions[2] have shown that explosive strain may release an adequate portion of energy in the form of S waves, so that observed radiation patterns may well be accounted for by an explosive (or implosive) phase transition.

For a reaction to be quasi-instantaneous, free energy must decrease and some of the heat liberated must remain in the system, thereby increasing temperature and rate of reaction. If, therefore, phase transitions are a source of seismic energy, mineral phases in the mantle must become metastable before reaction. A mineral phase could become metastable in the process of moving to a new pressure–temperature (PT) environment. Vertical migration of mantle material appears to be the only mechanism which could substantially change the PT environment.

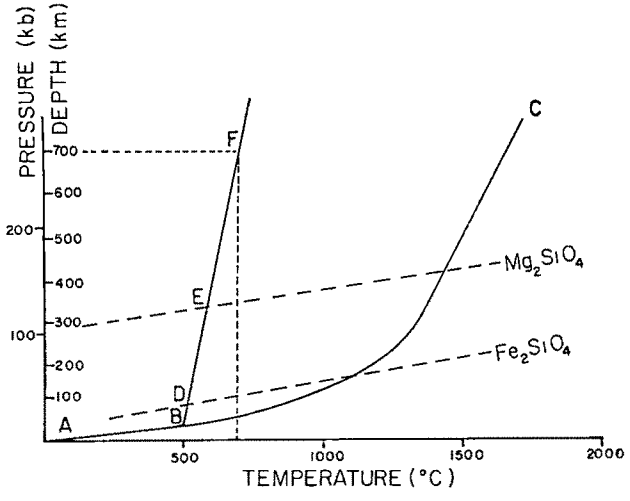

Fig 1. Pressure-temperature variation in the crust and upper mantle BF is the adiabatic dT/dP gradient[3]. ABC is the stable mantle dT/dP gradient[4]. Mg_2SiO_4 indicates the olivine-spinel transition curve for forsterite and Fe_2SiO_4 that for fayalite Therefore D and E indicate the depths in a descending current at which fayalite and forsterite would change to spinel or become metastable Point F indicates the depth on the adiabatic gradient corresponding to 700° C

Several processes might initiate vertical currents in the mantle. For example, a local increase in density near the top of the mantle would result in a gravity potential capable of initiating a downward current. Increase in density could be due to local cooling possibly caused by upward migration of radioactive isotopes and consequent impoverishment in heat sources during crustal differentiation. Downward segregation of mafic constituents during granite formation would also lead to local density changes in the upper mantle. Finally, rapid sedimentation and consequent isostatic adjustment could initiate a downward migration of mantle material. Now, pressure–volume changes in the mantle are usually considered to be adiabatic. Therefore, the adiabatic (dT/dP) gradient will determine temperature in a descending current initiated by any of the mechanisms already described. Since the adiabatic gradient[3] (Fig. 1, BEF) is less than the estimated dT/dP gradient in the stable mantle[4] (Fig. 1, ABC), the temperature in the sinking current would become progressively less than the temperature in the adjacent mantle. The downward driving potential for a mantle current therefore increases with depth so that a current, once initiated, should persist provided that heat exchange remains negligible.

The exact composition of the mantle is unknown, but olivine is generally considered to be a major constituent. Both forsterite and fayalite have high-pressure spinel polymorphs[5,6] and consequently might become metastable during downward migration in the mantle. Assuming a temperature before migration similar to that at the top of the stable mantle, transition from olivine to spinel would occur at a depth determined by the intersection of the olivine–spinel dT/dP transition curve and the adiabatic gradient; that is, point E in Fig. 1 for forsterite and point D for fayalite. The activation energy for reactions involving lattice rearrangement in the solid state is high. Consequently, the probability of transition at equilibrium could approach zero, so that olivine in the mantle would become increasingly metastable as it moved through and past equilibrium along the PT path determined by the adiabatic gradient BF (Fig. 1). However, with continued downward migration the temperature of the metastable olivine, and consequently the probability of transition, would increase and the spinel phase would eventually be nucleated. If, as is generally believed, mantle processes are essentially adiabatic, heat liberated during the reaction would accumulate within the system, thereby increasing nucleation and reaction rate until the transition became implosive.

We have suggested this mechanism[7] for generation of earthquakes by quasi-instantaneous phase transition from a metastable state as a possible basis for future investigation: a new investigation of the olivine–spinel transition in fayalite[6] suggests that the reaction is completely reversible at temperatures greater than 700° C. If this is so, the temperature in the upper mantle where downward migration might start must be considerably less than 700° C. Assuming the stable mantle dT/dP gradient proposed by Verhoogen[4] (Fig. 1) the temperature at the Mohorovičič discontinuity, that is at a depth of 40 km, would be about 500° C. If downward migration is initiated from such an environment, and temperature in the descending current is determined by the adiabatic dT/dP gradient[3] (Fig. 1), the temperature would reach 700° C at a depth of 700 km. On the basis of these data, then, earthquakes could not be generated below a depth of 700 km.

We suggest that more information on the kinetics of possible solid state reactions in the mantle be made available to support existing data. In particular, the response of powdered fayalite or its spinel polymorph to heat and pressure may not be comparable to the response of olivine and spinel crystals in the mantle. Also, atmospheric carbon dioxide trapped in mineral powders could take part in laboratory reactions and so act as a catalyst. Yet again, results obtained from fayalite may not be applicable to forsterite, believed to be the predominant component of mantle olivine. Nevertheless, this example shows that the temperature at any depth in a sinking current can be inferred once adequate data are available. Furthermore, the relation, if any, between earthquake foci and density discontinuities should be investigated because the depth and nature of phase transitions might be inferred from such information. Finally, first motion and energy data should be analysed without prior assumption of any specific pattern.

PHYSICS

Laser Probing the Lower Atmosphere

Synge[1] first suggested in 1930 that density measurements could be made of the lower atmosphere by observing the light scattered from the beam of a search-light. Elterman[2] in 1950 and onwards has operated the method in New Mexico with many improvements of the techniques. Fiocco and Smullins[3] in 1963 substituted a laser beam for the search-light beam and achieved comparable results. The equipment used in the experiments described here was planned in 1962 and erected in Kingston, Jamaica, 18° N., 77° W.

The equipment used was an optical radar suitable for detecting the amount of atmospheric scattering (the height to which such equipment could probe was limited only by its sensitivity). A Q-spoiled ruby laser was used as the transmitter. The output energy of the latter was about 6 J for each shot, which consisted of five giant pulses in a 5-μsec interval. The laser output beam passed through a rapid shutter which closed within 150 μsec after the shot and so cut off any fluorescence from the ruby. The beam was optically collimated to give a half beam-width of about 0·15 mrad and transmitted vertically. The receiving system for the light scattered back by the atmospheric constituents was essentially a 50-cm diameter astronomical telescope. The half beam-width of the receiving cone was adjusted to be about 0·2 mrad by altering the size of the aperture in the focal plane. The light passing through the aperture was filtered by interference filters of either 20 Å or 3 Å band-width, and then detected by a photomultiplier. The output of the photomultiplier was photographically recorded from an oscilloscope screen Each detected photon produced a pulse which was recorded as a y deflexion on a time base displayed in the form of a raster.

After a series of shots, the total number of photons counted at each height (h in km) was corrected for the background count. The product Nh^2 was then proportional to the scattering power of the atmosphere at that height. A typical night's result of scattering power versus height is shown in Fig. 1.

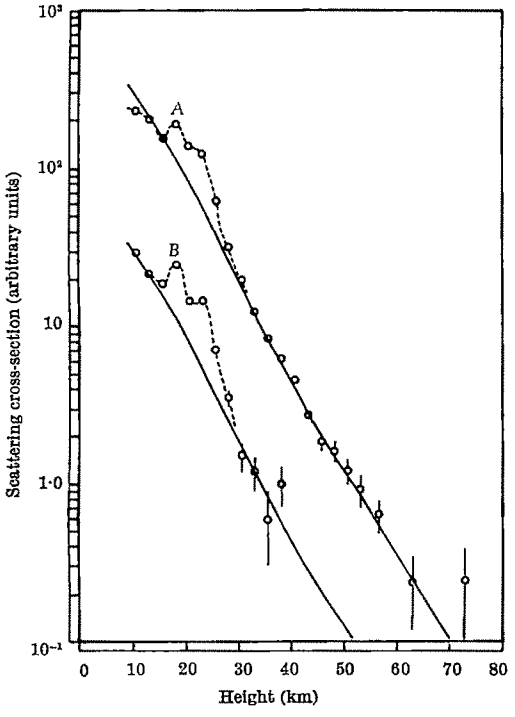

Fig. 1. Variations of scattering cross-section with height. A, Direct; B, with polarizing filter. ———, Standard atmosphere, ---O---, experimental observations

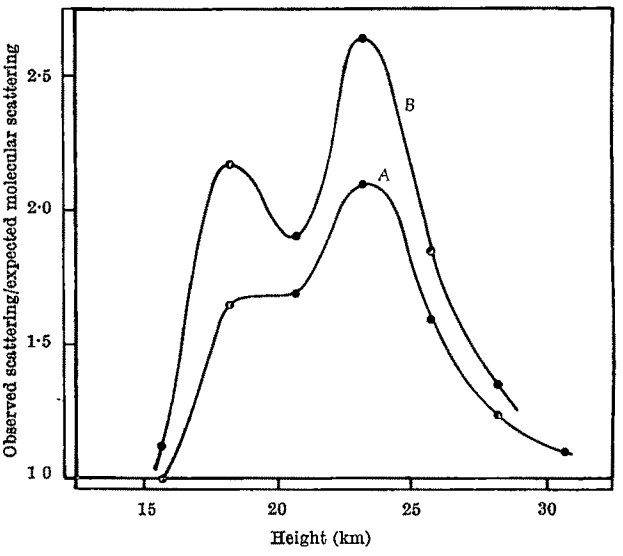

Fig. 2. Variations with height of the ratio of observed scattering to expected molecular scattering. A, Direct; B, with polarizing filter

The experimental points are shown in curve A, in conjunction with the theoretical curve of the amount of Rayleigh scattering to be expected from the molecules of the atmosphere, assuming the expected properties of the atmosphere above Jamaica. The ordinate scales have been chosen such that the experimental points and the curve fit at about 30 km. Excessive scattering occurs in the 15–30 km region. This is similar to the results obtained by Fiocco and Grams[4]. In our results, however, there is evidence of two peaks of extra scattering, one at 18 km and the other at 25 km; such a finding is in accordance with the results obtained by Elterman and Campbell[5] using the search-light technique.

In order to examine these peaks in more detail, efforts were made to accentuate their existence. The laser beam was highly polarized ; aerosol or dust particles could be expected to depolarize the returned signal more than air molecules. Consequently, a series of shots were fired with a polarizing filter over the detector. The filter was orientated in such a way as to reduce the signal received from the molecular scattering to a minimum. The results of this series of experiments are shown in curve B of Fig. 1. It will be seen that the molecular scatter was reduced by a factor of about twelve while the dust layer signal was only reduced by about eight. This point is emphasized in Fig. 2, where the ratio of total scatter to expected molecular scatter is shown.

It should be noted that in this series of experiments, our transmitting and receiving beams were very narrow and did not overlap completely below 10 km. Observations can easily be made at lower levels by increasing the receiving beam width.

The results from between 30 km and 60 km offer a means of determining the scale height and hence the temperature in this region. The scale height is found to change from 6·1 km at about 35 km to 7·6 km at about 45 km, which indicates a temperature change from 208° K to 260° K—as would be expected. The results from above 60 km are as yet only very approximate.

Fiocco and Smullins[3], who worked near Boston, Mass., where conditions may be different, have reported evidence for scattering from regions between 80 and 120 km during or after meteor showers. We have not as yet made observations at the time of meteor showers. The signal which we received from around 30 km was about 100 times as great as that received by Fiocco and Smullins, so that any signal from the 80–120 km region detected by them should have been easily recognized by our equipment. However, although there was a slight indication that there was

more scattering from these levels than would have been expected from simple Rayleigh scattering by air molecules, no scattering comparable with that observed by Fiocco and Smullins was, in fact, detected. We intend to make observations in Jamaica during the forthcoming meteor showers to see if similar echoes are detected. We shall also be able to improve the accuracy of our observations at greater heights by reducing the signal-to-noise ratio by cooling the photomultiplier.

The results described here are of a preliminary nature and the full capabilities of the equipment have not yet been attained. In spite of the brightness of the daytime sky, reliable measurements have been made in daylight up to about 30 km and will be extended to 40 km in the near future. This means that it should be easy to observe steadily the aerosol layers for 24 h a day—given cloudless days. It is of interest to note that we had to 'tune' the laser thermally in order to avoid the water–vapour absorption band at 6943·8 Å.

Transmission of Indian Mica between 300 and 1,000 mμ and its Visual Classification

India produces ruby and green muscovite mica. Depending on the 'stains' and inclusions each is visually classified into a number of groups, namely, 'clear', 'good-stained', 'fair-stained', 'stained', 'heavily stained', 'densely stained', 'black-dotted', 'black-spotted', etc. It has been reported[1,2] that any visual classification has little bearing on the electrical properties of mica. Little information is available on the transmission of natural mica in the region of 300–1,000 mμ. Popper[3] has reported that the absorption in the ultra-violet region of the Congo green muscovite is more than that of the Rhodesian ruby and synthetic mica. Spectral absorption for Russian muscovite and phlogopite micas in the region of 220–1,200 mμ was studied by Grum-Grzhimails *et al.*[4] and Melankholin[5]. To our knowledge, no such investigation of the spectral transmission of Indian muscovite has yet been reported. This communication reports our investigations of the optical transmission of Indian muscovite and its correlation with the visual classification.

Samples of different grades of muscovite were obtained from the Bihar, Madras and Rajasthan regions—the three main mica-producing states of India. The samples were thoroughly cleaned with benzene (B.D.H.) and stored in a desiccator for 24 h before any optical measurements were undertaken. Spectroradiometric measurements were carried out in the region of 300–1,000 mμ using a Hilger 'Uvispeck' spectrophotometer provided with a quartz prism. Transmission curves for various mica samples are given in Figs. 1–4.

Table 1. Chemical Analysis of Ruby and Green Muscovite Mica

	Ruby muscovite mica (per cent)	Green muscovite mica (per cent)
SiO_2	43·87	43·86
TiO_2	0·24	0·22
Al_2O_3	36 00	33·27
Fe_2O_3	1 73	5·29
FeO	0 25	0·70
MgO	0 53	1·14
K_2O	9 78	9 31
Na_2O	0 88	0 40
L O 1	7·15	7·03

Transmission of ruby muscovite between 300 and 1,000 mμ is more than for green muscovite mica (Figs. 1 and 3). Our findings, that the 'cut-off' frequency for the green muscovite is greater than that of the ruby variety, are in full agreement with those of Popper[3]. Popper[3] and Grum-Grzhimails *et al.*[4,5] have reported that cut-off frequency in the ultra-violet region depends on the quantity of iron present in the sample. The higher cut-off frequency as well as the lower transparency for green muscovite can therefore be attributed to a higher iron content, as is evident from the chemical analysis (Table 1). The content of FeO and Fe_2O_3 in the ruby and green muscovite is not linearly related to the absorption coefficient. It is

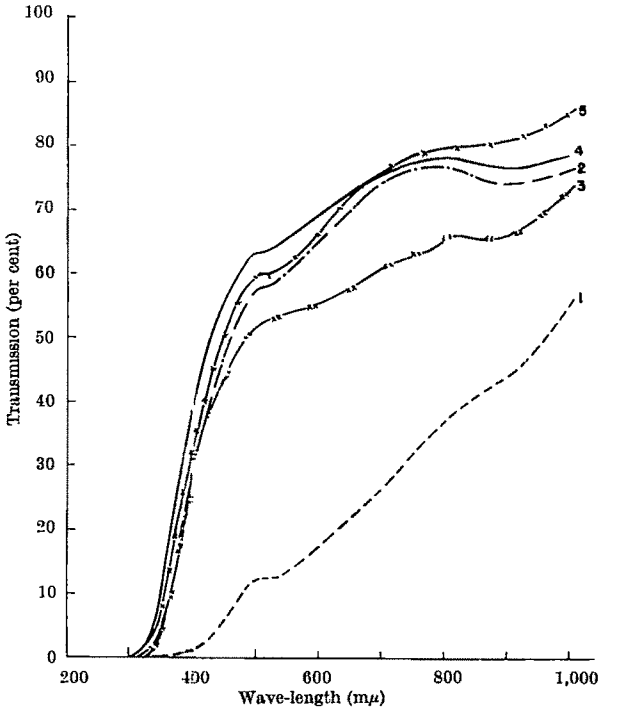

Fig. 1. Madras mica: (1) green (0·310 mm thickness); (2) ruby clear (0 310 mm); (3) green (0 219 mm); (4) ruby *A Q* (0 207 mm); (5) ruby *BQ* (0 207 mm)

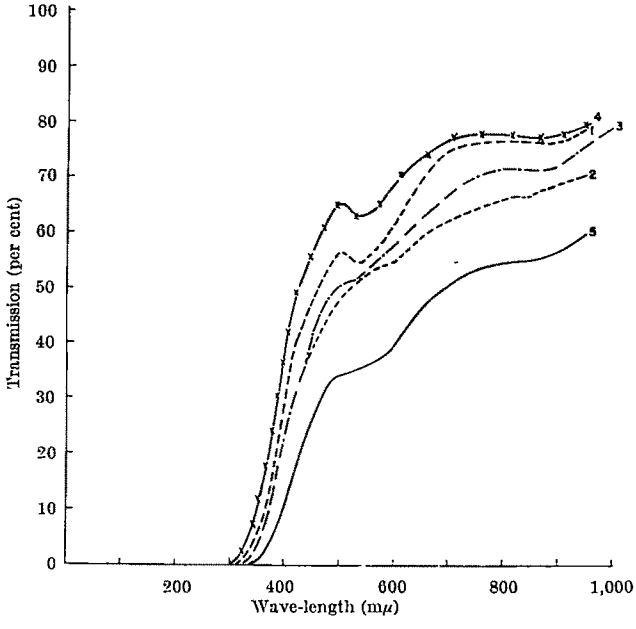

Fig. 2. Bihar ruby mica. (1) stained (0 263 mm thickness); (2) densely stained (0 263 mm); (3) black-dotted (0 501 mm), (4) stained *B* (0·219 mm); (5) densely stained (0 482 mm)

possible that the absorption spectra of muscovite might depend on the lattice parameters, especially on the presence of other elements in the octahedral layer.

Transparency in the ultra-violet region of the green muscovite of the same origin varies from sample to sample. In Fig. 3 it can be seen that two samples of green muscovite from the Rajasthan region which have similar thickness, differ in transparency, although the cut-off frequency is more or less the same. Green muscovite of the same visual quality but from Madras and Rajasthan regions differs in transparency and cut-off frequency in the ultra-violet region (Fig. 3). If the transparency is an indication of the iron content as advocated by Popper and others[3,5], it may be concluded that samples of green muscovite of the same quality from different regions, or even from the same region, differ in iron content. The cut-off frequency of ruby muscovite (clear) from the Bihar region is lower than that from the Rajasthan region, although the difference in transparency is small.

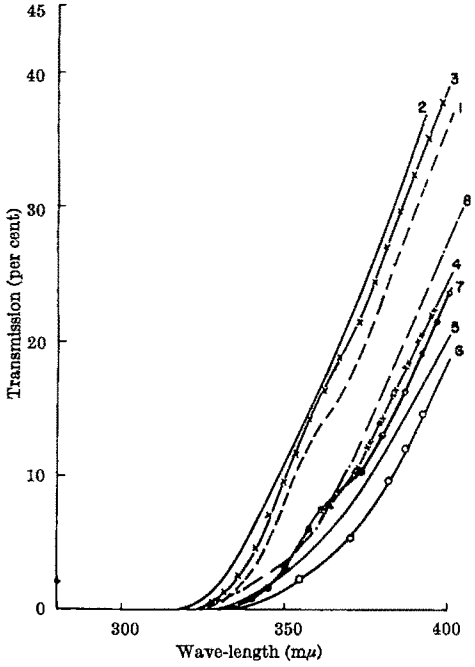

Fig 3. (1) Rajasthan green clear (0 196 mm); (2) Rajasthan ruby clear (0·196 mm); (3) Rajasthan green clear (0 190 mm); (4) Rajasthan ruby clear (0 310 mm); (5) Rajasthan heavily stained (0 311 mm); (6) Rajasthan green clear (0·335 mm); (7) Madras green clear (0 335 mm); (8) Bihar ruby clear (0·321 mm)

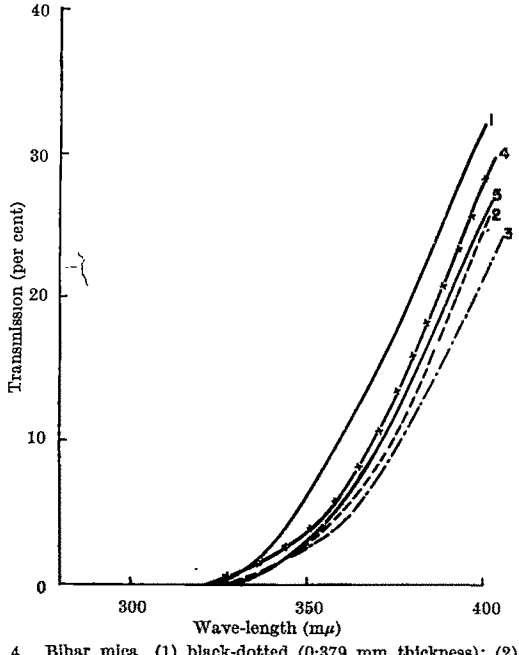

Fig. 4. Bihar mica (1) black-dotted (0·379 mm thickness); (2) fair stained (0 364 mm), (3) stained (0·363 mm), (4) ruby clear (0 312 mm), (5) Rajasthan ruby clear (0·312 mm)

Stains and other inclusions affect the transparency of muscovite and there appears to be some relationship between transparency and the visual classification of mica. Inclusions do not affect the cut-off frequency but, in general, the greater the 'stain'—that is, the lower the mica in the visual grade—the less transparent is the mica (Figs. 1 and 2). 'Black-dotted' mica appears to be anomalous in this respect; even though it is thicker it transmits more light than does 'densely-stained' mica—a superior quality mica according to the visual classification. As regards transparency in the ultra-violet region, 'black-dotted' mica is superior even to 'fair-stained' and 'stained' quality mica.

The transparency of various 'fair-stained' muscovite in the ultra-violet region, like 'stained' and 'fair-stained' (Fig. 4), ruby *AQ* and ruby *BQ* (Fig. 1), does not differ very much. These micas may, therefore, be grouped in the 'stained' class, as small variations in air or gas inclusions do not have appreciable effect on transparency.

The nature of the transmission curves for both ruby and green muscovite is similar irrespective of the presence of stains and inclusions. The curves show narrow low maxima (absorption) at about 525 and 875 mμ. Green muscovite shows some inflexion at about 360 mμ. These may be due to the presence of iron minerals in the muscovite lamina. As the nature of the iron minerals in the mica lamina was not identified, the foregoing hypothesis may be considered inconclusive.

Visualization of Low-speed Flow using Suspended Plastic Particles

Photography of particles suspended in a fluid often gives a more complete and easily comprehensible record of the events associated with the passage of fluid around an object than can be achieved through measurements of force, velocity, or pressure. In practice, however, smoke trails and most other methods of flow marking[1–4] are both cumbersome and non-quantitative. In response to the problem of recording flow patterns around airfoils at Reynolds numbers of about 100, we have devised a new technique, using plastic particles suspended in a revolving bowl of brine and illuminated by pulses of light. This system produces photographs of steady flow patterns at Reynolds numbers between 30 and 300, with both speed and direction of flow indicated in the pictures (Fig. 1).

For use as flow markers, particles must (1) be of convenient size, (2) reflect light, and (3) be of a density suitable for suspending in the fluid. The following method produced particles slightly denser than water having an intense yellow colour in visible light and a bright yellow fluorescence under ultra-violet illumination. A slurry of the compounds listed in Table 1 was poured into gelatine capsules and polymerized at 60° C overnight. Since the 'STC' sank to the bottoms of the capsules, the upper, colourless portions of the plastic as well as the gelatine envelopes were cut away and discarded. The remaining bright yellow plastic was crushed in a cold mortar or

Table 1. COMPOSITION OF THE PLASTIC

(3) α,α-Azodiisobutyronitrile, 0·5 per cent by weight dissolved in the monomer mixture. Function: catalyst. Source: Eastman (No. 6400), Rochester, N.Y.
(4) 'STC' about 20 per cent by weight of the monomer mixture. Function: colour; 'STC' is a 'fluorescent brightening agent' soluble in organic solvents. Source: Geigy Industrial Chemicals, Saw Mill River Road, Ardsley, N.Y.

powder mill and the particles sifted to sort them by size. Fig. 1, for example, was made with particles 0·2–0·5 mm in diameter.

Fig. 2 illustrates the flow chamber used to move fluid past the models; the bowl itself was a transparent 'Perspex' cylinder, 4 in. in diameter and 2·5 in. high. (The use of a revolving bowl was suggested by B. Howland in a personal communication, and the arrangement of bowl and motor drive was similar to that of Howland, Pitts, and Gesteland[5].) Particles were held in suspension by adjusting the density of the fluid; the final solution contained about 19 g of salt per 100 c.c. of aqueous solution. A slight vertical density gradient helped to keep the particles from sinking to the bottom or rising to the surface. An individual bath was serviceable for up to 2 days; the particles were recovered by filtration and re-used, generally without drying. Initially, the dry particles had to be shaken in degassed water or brine to remove adhering air bubbles.

Airfoils were made of transparent 'Perspex' in order to minimize shadows in the photographs. These models were held in the brine by a brass support at the axis of rotation of the bowl. Both the size of the model and its distance from the centre of the bowl as well as the rotation rate were chosen to give the desired Reynolds number. Light from either a mechanical or an electronic stroboscope passed through a curved slit perpendicular to the camera axis and parallel to the direction of flow; thus the light struck the particles as the latter traversed a plane which crossed the model. Use of a stroboscope gave a dotted line for the path of each particle, and consequently both speed and direction of flow at all points around a model were recorded. A General Radio Co. 'Strobotac', type 1531-*A*, provided adequate illumination at flashing rates up to 12/sec for photographs taken at *f*/5·6 on Eastman 'Tri-*X*' film. Supporting structures were coated with non-reflective black paint to reduce scattered light.

The present scheme for flow visualization may be modified to extend its usefulness. The composition of the particles (Table 1) represents only an empirical solution to a specific problem. Methacrylate monomers with side-chains shorter than hexyl produce denser and harder polymers; longer side chains yield lighter and softer plastics. The choice of colouring substances is limited only to those that can be either suspended or dissolved in the monomer mixture without inhibiting polymerization. The mixing of fluids from separate sources may be studied with particles of different colours.

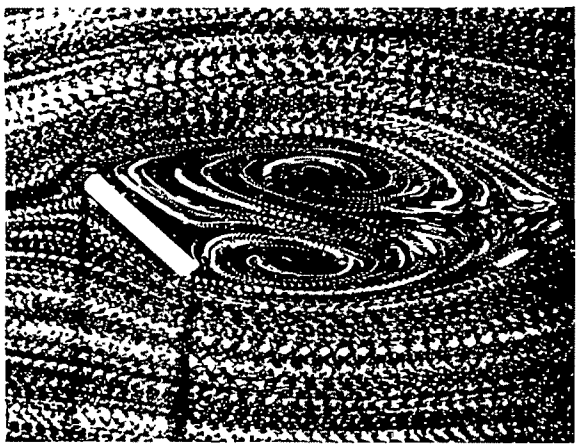

Fig. 1. Flow around a stalled airfoil at a Reynolds number of 140. The location of the model has been marked on the photograph, since the actual model was transparent. The shadows below the edges of the airfoil are caused by the bevelling of these edges. Chord: 8·5 mm. Flashing rate: 11 7/sec. Exposure: 4 sec

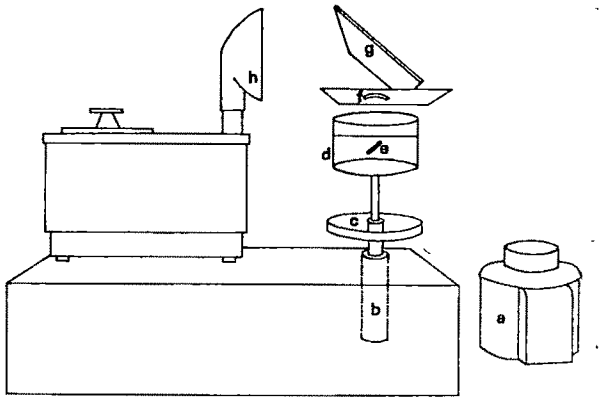

Fig. 2. The flow chamber and associated components. *a*, 'Variac' speed control, *b*, variable speed motor; *c*, flywheel; *d*, 'Perspex' bowl; *e*, model; *f*, curved slit in cardboard baffle; *g*, mirror; *h*, lamp housing of 'Strobotac'. The camera (not shown) was aimed at the model on a line normal to the plane of the diagram

Similarly, other parameters of the system may be varied. Higher Reynolds numbers may be achieved using either higher flow speeds or larger models, while lower velocities or the addition of glycerin to the fluid reduce the Reynolds number. Since the suspension of plastic particles is extremely stable, operation at very low speeds presents no special problems. Intensity of illumination is not limiting either: a mechanical stroboscope using a revolving sector disk can be used; while this variant gives dashes instead of dots on the photographs, it permits the use of a lantern slide projector as a high-intensity light source. Extraneous reflexions from incident illumination may be avoided, if necessary, by using an ultra-violet light source together with a suitable filter for the camera lens. The basic arrangement, with continuous illumination, should be well suited to cinematography for demonstration of the temporal structure of turbulence and related phenomena. Similarly, if force is measured simultaneously, changes in the appearance of flow around an object could be compared with the net reaction of the fluid on the object.

This method of flow visualization should also be convenient for laboratory investigations of the microhabitats encountered by limnologists and biological oceanographers.

Dispersion Relation in Liquid Helium

THE normal mode representation[1] of the excitations in liquid helium describes the thermodynamic behaviour below the lambda point as the vibrational modes among a temperature dependent population of diatomic rotors. The excitation spectrum has now been obtained from the

theory on the assumption of an observed empirical relation.

The complete partition function, including phonons, is:

$$f = \Sigma \frac{(v + n - 1)!}{v!(n-1)!} \exp\left(-\left(v + \frac{n}{2}\right)\frac{h\nu_0}{kT}\right) \times \Sigma \exp\left(-\left(v + \frac{1}{2}\right)\frac{h\nu_0}{kT}\right)$$

v is the vibrational quantum number, n the number of dimensions and ν_0 the fundamental frequency of the harmonic oscillator. States above the ground state may be summed to give:

$$f = (1 - \exp(-h\nu_0/kT))^{-(n+1)}$$

From this expression, the thermodynamic functions may be obtained if n is defined as the number of states per atomic pair of thermally excited rotors:

$$n = \frac{\sum_{2,4\ldots} (2J + 1) \exp(-J(J+1)B/kT)}{\sum_{0,2,4\ldots} (2J + 1) \exp(-J(J+1)B/kT)} W$$

where B is the constant for a rigid rotor composed of two helium atoms with nearest neighbour spacing. W then is the number of ways pairs can be formed with nearest neighbour spacings ($W = 60$). The partition function can be re-expressed as:

$$f = \sum_v \omega \exp(-vh\nu_0/kT)$$

$$\omega = \frac{(v + n)!}{v!\,n!}$$

The excitation may be defined by the following relation:

$$\sum_v \exp(-\varepsilon/kT) \equiv \sum_v \omega \exp(-vh\nu_0/kT)$$

Equating terms and rearranging:

$$\exp(\varepsilon) = \exp(vh\nu_0 - kT \log \omega)$$

$$\varepsilon = vh\nu_0 - kT \log \omega$$

An additional relation must be used to eliminate the temperature from the dispersion relation. A comparison of the empirical dispersion relation with the internal energy leads to the observation that $c_2 p = kT$ at the upper limit of the phonon region and again at p_0 and T_λ (where c_2 is the velocity of second sound near 1° K). Above the lambda temperature the heat capacity rapidly returns to the Debye value, and above p_0 the dispersion curve is straight and parallel to the low-temperature phonon line (Fig. 1). In the normal mode representation, the lambda point is achieved when the number of excitations equals the number of particles. In the dispersion relation, ω will achieve a maximum value and become constant. The excitation energy will thereafter be linear with momentum, having a slope determined by the velocity of first sound.

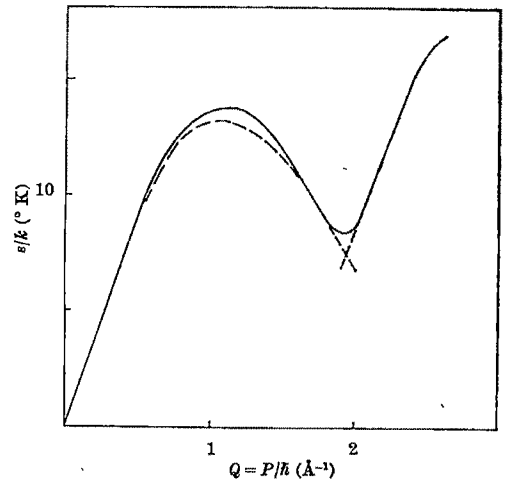

Fig. 1. Dispersion relation. Continuous curve, neutron scattering; broken curve, present theory

The equivalence of momentum and temperature is therefore assumed:

$$\frac{kT}{c_2 p} = \frac{c_1 kT}{c_2 vh\nu_0} = 1$$

The dispersion relation then takes the form:

$$\varepsilon = vh\nu_0\left(1 - \frac{c_2}{c_1}\log\omega\right)$$

The degeneracy is a function of n, which is temperature dependent. The same substitution renders n a function of v.

$$n = \frac{\sum_{2,4\ldots} (2J + 1) \exp(-J(J+1)Bc_1/c_2 vh\nu_0)}{\sum_{0,2,4\ldots} (2J + 1) \exp(-J(J+1)Bc_1/c_2 vh\nu_0)}$$

The resulting excitation spectrum is compared with the results of neutron spectroscopy[2] in Fig. 1.

The minimum of the dispersion curve at p_0 then represents the maximum value of ω, which will correspond to the case in which the number of particles equals the number of states. From this, the coherence length can be estimated. At p_0, $v = 4$ and $n = 27$ giving $\omega = 35{,}000$. The number of atoms participating is then 70,000. If these form a sphere, the radius would be 26 atoms or a distance of 100 Å. Such a size approaches the size of the vortices reported by Rayfield and Reif[3].

Important Feature of Time Modulation

Time modulation, where information is conveyed by changing the time between similar parts of the modulated wave-train rather than by the frequency of occurrence, has a feature which is of great importance at the de-modulation stage. This can best be demonstrated by considering a common method of de-modulating a frequency-modulated wave-train and comparing it with a method which is particularly simple to use where the wave-train is time-modulated. Fig. 1 shows a frequency modulated wave-train with a step change in frequency; a common and representative method of de-modulation is shown in Fig. 2. The box represents a device which produces a pulse of current (di) of short and controlled duration for each pulse of the input wave-train. The mean current flowing through R is, therefore, $n \times di$ where n is the pulse-recurrence frequency. The mean potential across R is $n \times di \times R$ and is proportional to the mean value of the pulse frequency and hence represents the original modulation waveform. The value of c does not affect the mean value of current but has a marked effect on the transient performance of the circuit. If it is assumed that the current pulse has a negligible duration compared with the repetition frequency, then the waveform across the capacitor will be as shown in Fig. 1. The fall in potential between pulses is represented by the expression $v = V(\varepsilon - t/cR)$ where v is the capacitor potential at any time t after an input pulse at which time $v = V$. The potential of the capacitor, therefore, falls exponentially with time with a time constant given by the product of c and R. In most situations it is desirable to recover the original modulating waveform undisturbed by components of the carrier, and the difficulty is to choose $c.R$ so that the carrier frequency components (ripple) are at an acceptable level while maintaining a good transient performance of the de-modulated waveform. Often a simple resistance–capacitance filter will not give sufficiently good performance and elaborate low-pass filters must be used. The filters have, up to the present, always used

inductive elements which are not as convenient to use as resistive–capacitance components (they must in general be specially wound) and cannot be made in 'integrated circuit' form. (This method of construction involves making the components and their interconnexions at the same time, often on a common surface.)

Time modulation and de-modulation may be thought of in geometrical form. The modulator (Fig. 3) contains two essential features; a section which causes a potential to rise linearly with time (the reference waveform) and a voltage comparator. The input or modulating voltage must be arranged to be of one polarity only; if it is of either polarity a fixed bias must be added to it to make it conform to this restriction. The circuit is arranged so that when the reference waveform reaches the same potential as the input voltage (as sensed by the voltage comparator) it is returned to zero within a negligible time-interval and, at the same moment, an output pulse is emitted. Thus the time between output pulses is a linear function of the magnitude of the input waveform, and time modulation is achieved. The de-modulator contains a similar device to the modulator and creates a potential which rises at the same rate as the reference waveform in the modulator. The de-modulator waveform is called the generating waveform (Fig. 3). If an incoming pulse has just occurred, the generating waveform will, as will be explained later, be at zero and will have just started to rise. When the next pulse occurs, the generating waveform will have reached the same potential as the reference waveform in the modulator. This new input pulse first connects the generating waveform (via an electronic switch, Fig. 4) to a storage capacitor and then returns the generating waveform to zero. The constants of the circuit can be arranged so that the potential of the storage capacitor is brought into equilibrium in a time short compared with the pulse-recurrence time. It can also be arranged that the output circuit connected to the storage capacitor draws so little current that the potential of the latter is virtually unchanged during the pulse-recurrence time. The storage capacitor, therefore, takes on the value of the generating waveform at the time of an input pulse and holds this value until the next one occurs. If there has been no change in the modulating waveform between pulses there will be a negligible change in the potential of the storage capacitor. Thus the de-modulator has a 'ripple' voltage proportional to the difference in modulating potential between carrier pulses.

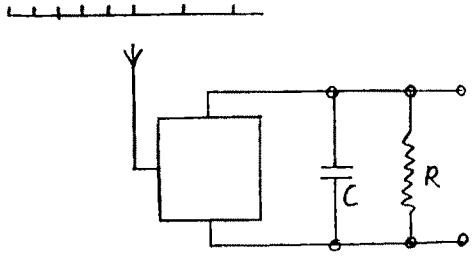

Fig 2. Frequency de-modulator. Block diagram showing input wave-train

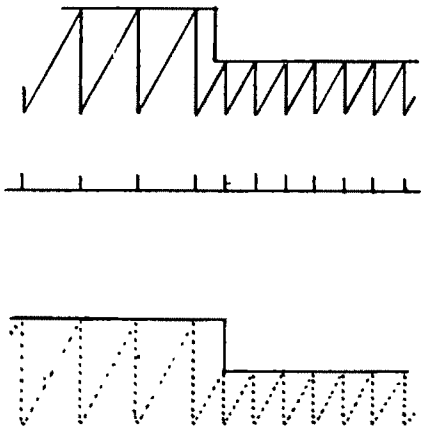

Fig 3 Time modulation waveforms. Top: modulation waveform in contact with reference waveform. Middle: carrier wave-train. Bottom: de-modulated waveform in contact with (dotted) generating waveform

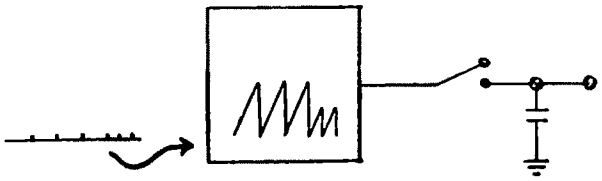

Fig. 4. Time de-modulator: Block diagram showing input wave-train, generating waveform electronic switch and storage capacitor

The system can be described in general terms as one in which the modulating waveform is sampled at various instants and the value transmitted to the de-modulator, which immediately assumes this value at its output and holds it until the next value is transmitted. It conveys the maximum information that can be transmitted with a simple pulse-train and the de-modulation makes the only assumption that can be generally true. The system may be realized in various forms and is very suitable for circuits using transistors as the active circuit elements. As it uses no inductive elements it is suitable for 'integrated circuit' construction. The performance of a simple form of the system (26 transistors in total for modulator and de-modulator combined) is shown in Fig. 5. The mean period of the modulated wave-train is 10 msec (~ 100 c/s) and the time deviation is ± 2 msec. The top row of waveforms (Fig. 5) shows the modulating waveforms which are, reading from left to right, 10 c/s sine wave, 10 c/s square wave, electrocardiograph-type waveform[1] with a period of 1 sec. The middle row shows the de-modulated waveforms with no additional smoothing, while the bottom row shows the effect on the de-modulated waveforms of a resistive capacitive time constant of 5 msec. It can be seen that for many purposes no additional filtration is needed after the storage capacitor and hence the system has a very good transient response. If some additional filtration is needed, however, a very simple filter is all that is required. If the modulating frequency is made much higher than the 10 : 1 ratio of Fig. 5, then additional filtration may usually be omitted. The electrocardiograph-type waveform demonstrates the lack of ripple at low amplitude changes and the system is most suitable for this important type of medical recording, where much of the useful information is contained in the low-level changes of the wave and little in the 'spike' ('*R*' wave) itself.

Though the de-modulating system has been described in terms of time modulated waveforms, it could be used with frequency modulated information and thus extend the advantages of the system to existing frequency modulated magnetic tapes. If the de-modulator were simply used on frequency modulated material, there would be an error

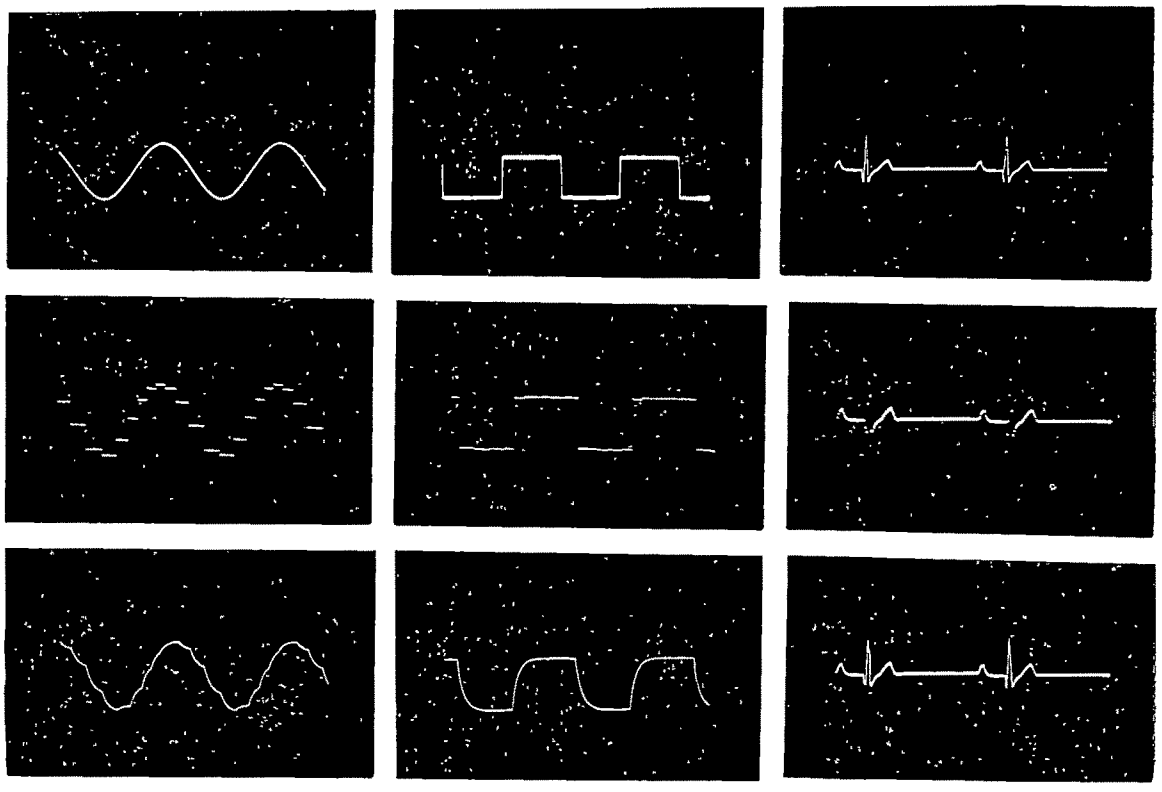

Fig. 5. Carrier mean period of 10 m/sec. Top row. modulating waveforms (10 c/s sine, square wave and 1 c/s electrocardiogram-type waveform). Middle row: de-modulated waveforms, no additional filtering Bottom row: de-modulated waveforms, 5 msec time constant filter

since frequency modulation is a function of $1/t$ (where t is the periodic time) rather than a direct function of t. This might not be too serious were the frequency deviation small, but if it were large the errors would probably be unacceptable. The errors can be eliminated by causing the generating voltage to have a value proportional to $1/t$. Work is in hand to design such a device.

METEOROLOGY

Hydrogen Content of the Air

A series of experiments carried out by Glueckauf and Kitt in the 1950s (ref. 1) showed that hydrogen was present in the atmosphere to the extent of about 0·6 parts per million by volume, and that the concentration was not constant. It was not clear whether or not the variations were correlated with meteorological conditions.

The distribution of atmospheric hydrogen is of interest, since there is a considerable influx of protons into the upper atmosphere in the form of the solar wind. It has been suggested[2] that a proportion of terrestrial water originated as protons from the Sun. On the other hand, it is likely that some of the free hydrogen produced by photolysis of water and hydrocarbons in the high atmosphere is able to escape from the Earth. Possible sources of hydrogen at the Earth's surface include natural gas, first suggested by Paneth in 1937, coal mines and industrial activity.

Various methods have been investigated here for detecting very small concentrations of hydrogen in a volume of air sufficiently small to be collected from an aircraft or balloon. A method was also required which would give a continuous record of the hydrogen concentration at a fixed station, and an apparatus which appears to be capable of satisfying both these requirements has now been developed. It has been used to give an almost continuous record of the hydrogen concentration in Cambridge air from September 17, 1965, until the time of writing.

The apparatus is based on the phosphoric acid electrolytic hygrometer, described by Goldsmith[3]. After being dried with silica gel and P_2O_5, a slow stream of air is drawn over heated palladous oxide, and then past the hygrometer. At 300° C, PdO oxidizes hydrogen and carbon monoxide, but not, so far as is known, hydrocarbons. The whole apparatus, apart from preliminary drying agents, is enclosed in a stainless steel tube to avoid contamination from adsorbed water. A zero reference is provided by drawing the incoming air through a bed of heated alumina granules, coated with palladium, for 50 min in every 100. (This material is supplied as 'Deoxo' for removing oxygen from a stream of hydrogen,

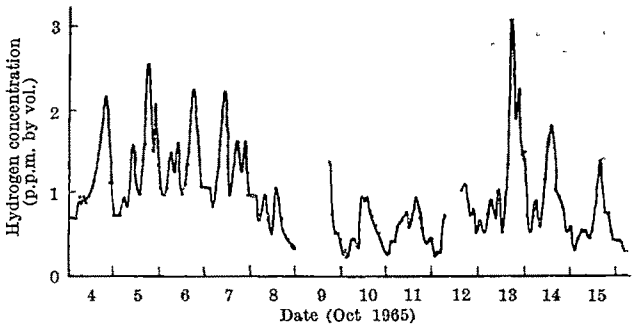

Fig. 1 Each point represents one 100-min cycle. The break on Oct. 9, 1965. was caused by a faulty time switch. On Oct. 12 the instrument was tested for sensitivity to methane

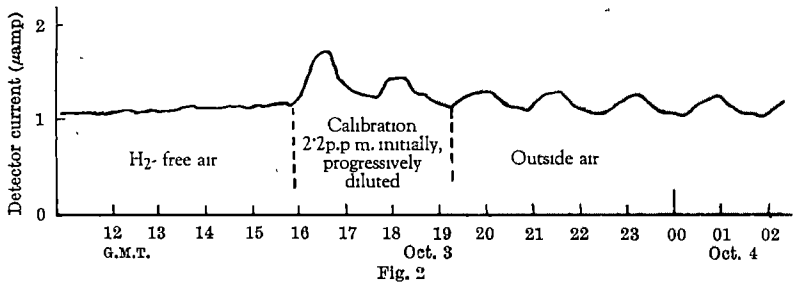

Fig. 2

but has been found equally effective the other way round.) The resulting trace on a pen recorder connected to the hygrometer is a square wave, distorted by the overall response time of the instrument, which is about 30 min.

It has been found that the hydrogen content of the atmosphere varies considerably. Extremely high values (> 2 p.p.m. by volume) are confined to the day and evening, and could well be attributed to exhaust fumes from the nearby road. During September 29–October 4 the apparatus was out of action while the P_2O_5 drying agent was changed, and the detector 'dried out' and calibrated with a sample of 0·027 c.c. of hydrogen mixed in 12 l. of hydrogen-free air (Fig. 2). It will be seen that the signal-to-noise ratio is adequate for atmospheric hydrogen measurement, while the cycling method eliminates errors due to long-term drift in the d.c. amplifier or detector. The results since then are shown in Fig. 1.

On October 12 the instrument was tested for sensitivity to methane, and found to be at least 10 times less sensitive than to hydrogen. A more precise test is intended later.

During October 4–7 the weather was fine, with clear nights, and mist in the mornings. A depression was moving past to the south, and south-easterly winds predominated. The night of October 7 was cloudy, and there was no mist on the mornings of October 8–13. During this time an anticyclone was centred over the Shetlands, with mainly north-easterly winds and cloudy nights. On October 13 and 14, fronts associated with a depression near Iceland passed over, and there was mist on the morning of October 14. Pressure began to rise again about midnight on October 14.

As far as can be judged from the short records available, it appears that anticyclonic conditions are associated with a low mean hydrogen concentration, and particularly with very low concentrations during the night. The possibility of contamination from vehicle exhausts cannot yet be ruled out, but the continuity of the readings from Sunday, October 10, to Monday, October 11, suggests that it is not serious. The wind was blowing from the direction of the road on both days. Large peaks of hydrogen concentration in the evening seem to be confined to nights on which mist forms. There is a marked diurnal variation, with a minimum about 0400 G.M.T. on most days. Whether this is of natural or artificial origin cannot yet be determined.

GEOLOGY

Age of the Anorthosites in the Norwegian Caledonian Chain

The age of the anorthosites in the Caledonides of Norway has been much discussed, and both a pre-Caledonian and a Caledonian age has been considered[1]. This communication directs attention to a possible interpretation of the age problem, based on observations in the Möre region, central Norway, and the Bergen district, southern Norway.

According to my investigations in the Möre region, we have here an important Pre-Cambrian Caledonian stratigraphic sequence[2]. Dykes and lens-shaped bodies of metadolerites are found in the lower part of this sequence, and genetically related amphibolites occur as layers in the middle part. Titaniferous iron ore deposits occur both in the metadolerites and in the amphibolites[3].

In the eastern part of the More region, near the border of the Cambro–Silurian Caledonian Trondheim region, lenses and layers of anorthosite occur in the upper part of the Pre-Cambrian sequence[4]. Titaniferous iron ore concentrations are also found in the anorthosites.

The Bergen District. The gneiss area on the coast west of Bergen can be interpreted as being the core of a Caledonian anticline[5]. The axis of the anticline has a east-south-easterly direction, and the plunge of the fold is eastward.

The gneiss core dips to the east below a schist formation (the minor Bergen arc[6], in which the city of Bergen is situated), and the schists dip below a gneiss formation. There is no distinct boundary between the schist formation and the gneisses, and beds of mica schist and quartzite occur in the gneisses, and layers of gneiss are found in the schist formation. Bodies of metadolerite and amphibolite occur in this sequence. Magnetite and ilmenite can be present in considerable amounts within the bodies.

The gneiss formation dips to the east under an anorthosite formation. Titaniferous iron ore deposits occur in the anorthosites.

A Cambro–Silurian Caledonian schist sequence (the fossiliferous major Bergen arc) lies east of the anorthosite formation. Here we have a depression of the plunge of the anticline, and farther to the east anorthosites, gneisses and schists once more follow.

In my opinion, the gneisses, schists and anorthosites west and east of the fossiliferous Cambro–Silurian sequence form the Pre-Cambrian part of a Caledonian stratigraphic sequence. The schists are traditionally considered Cambro–Silurian, but there is much evidence in the field concerning the connexion between the schists and the gneisses. Correlations have been made between the Cambro–Silurian sequences in the Trondheim region east of the Möre region and in the Bergen district[7], and a correlation can also be made between the Pre-Cambrian sequence in the Möre region and in the Bergen district.

According to this interpretation of the Möre region and the Bergen district, metadolerites, amphibolites and anorthosites, with titaniferous iron ore concentrations, have a corresponding stratigraphic position in the two areas. Metadolerites and amphibolites are found in the lower and middle parts of the Pre-Cambrian Caledonian stratigraphic sequence, and the anorthosites occur in the upper part of the sequence. They represent basic products of the early Caledonian igneous activity in late Pre-Cambrian time[8].

Phyllocarid Crustacean Fauna of European Aspect from the Devonian of Western Australia

A remarkable collection of about 400 specimens of phyllocarid crustaceans was made in 1963 by H. A. Toombs of the British Museum (Natural History), and K. Buller and E. Car of the Western Australian Museum. The material was collected at two localities from calcareous siltstone concretions in the Gogo Formation which yields a lower *Manticoceras* Zone (*Timanites angustus* Subzone) goniatite fauna of Frasnian 1α age, Upper Devonian[1-3]. The localities are: 1, Virgin Bore area, Gogo Station, 125° 54′ E., 18° 35′ S., and 2, Bugle Gap, 126° 02′ 15″ E, 18° 41′ S., both in the Fitzroy Basin, Kimberley Division of Western Australia. Preliminary identifications of the phyllocarids, together with the relative frequency of occurrence, are as follows:

Locality 1: *Montecaris lehmanni* Jux, abundant; *Montecaris sp. nov.* ?, a very rare, heavily tuberculate form; *Concavicaris sp. nov.* 1 *aff. C. elytroides* (Meek), rare; *Schugurocaris sp.*, rare.

Locality 2: *Concavicaris spp. nov.* 1 *and* 2, *Schugurocaris sp.*

The fauna of the Gogo Formation is stated to be "characterized by *Buchiola* and other pelecypods, numerous *Tentaculites*, small, straight nautiloids, ostracods and coccostean and crustacean remains, [the ammonoids] *Timanites* and *Koenenites*"[2]. The ammonoids and Foraminifera have recently been described, and Radiolaria and conodonts are also known to occur[3,4]. In addition to most of the foregoing, however, the locality 1 fauna in the present collection includes bryozoans, gastropods, a single specimen of a eurypterid best referred to *Rhenopterus* (determined by Dr. C. D. Waterston), and the following fish (determined by H. A. Toombs): antiarchs and arthrodires (under study by Dr. R. S. Miles), palaeoniscids (to be studied by Dr. B. Gardiner) and rhipidistians, as well as coprolites and problematica.

The phyllocarid fauna is important not only in being a unique association of genera, but also in being of European aspect. Thus *M. lehmanni* is otherwise known only from the Frasnian 1α of the Rhenish Schiefergebirge[5]. *Montecaris* is recorded from the Gedinnian and Famennian of Czechoslovakia, the Lower Frasnian of the Transvolga region of the U.S.S.R. (? = *Baituganocaris* Krestnovnikov) and possibly from the Upper Devonian of British Columbia[6]. *Eleutherocaris*, the other member of the Montecaridinae, is known only from the Frasnian Naples fauna of New York State, U.S.A. *Schugurocaris* (? = *Phasganocaris*) was described from the Lower Frasnian of the Transvolga/Urals[7], although it may occur in the Ludlovian of British Columbia and the Gedinnian and ?Emsian of Czechoslovakia[8]. *Concavicaris elytroides* occurs in the Famennian–Lower Mississippian of Oklahoma and Kentucky, but the genus ranges from Eifelian to Pennsylvanian of Czechoslovakia and the U.S.A.

The overwhelmingly European character of the Western Australian Devonian has been stressed by Teichert[9,10], and is apparent even in this small phyllocarid fauna. North American affinities are also indicated by the closely related genera and species mentioned here, but this is probably due to the derivation of both Australian and American faunas from common European stocks. Close affinity between the American and European ammonoid faunas is most clearly developed in the Frasnian[11]. Teichert's theory that the Australian faunas migrated from central Germany via south-east Asia has been criticized by Neaverson[12] but reaffirmed by Veevers[13].

The Australian and European phyllocarids mentioned here occur in platy, silty limestones or calcareous siltstones deposited in still waters in inter-reef basins[14,16]. Sedimentation was fine grained and continuous, and benthos was thereby inhibited. A platy sedimentary breccia, similar to those in the Schiefergebirge[15], has been collected from locality 2 and suggests that similar off-reef slumping took place.

This work, and the fuller description which it is hoped will follow, is being supported by National Science Foundation grant *G*24045 and the University of Glasgow.

METALLURGY

Enhancement of Ductility in α-Uranium

Circumstances have been identified where metals and alloys undergo large plastic extensions, that is, 100–1,000 per cent elongation, before rupture[1,2]. Such materials are termed[2] 'superplastic' and can be extremely sensitive to changes in strain-rate[3], thus having a high value of the exponent, n, in the relationship between strain-rate $\dot{\varepsilon}$ and stress σ described by $\dot{\varepsilon}^n = k\sigma$, where k is a constant. Generally, n has values $< 0{\cdot}3$ in conventional tensile or creep tests even at temperatures approaching the melting-point; but certain non-ferrous alloys[3], notably those near eutectoid composition in the aluminium–zinc system which extend by several times their original length, have values of n up to $\sim 0{\cdot}7$.

Where n approaches unity, deformation tends to viscous (Newtonian) flow and, in this event, large elongations are possible since there is no enhancement of the rate of diminution of cross-sectional area. A common circumstance where metals deform by viscous flow is where vacancy creep[4] occurs, but a rapid rate of straining is generally impossible even at temperatures close to the melting-point since stresses must be sufficiently small to prevent dislocation movement.

One method of making polycrystalline uranium of random orientation flow viscously at temperatures away from the melting temperature, for example, $< 450°$ C, is to irradiate it with neutrons[5]. Under stresses about $Y/100$ and irradiation at 100° C, α-uranium exhibits a steady-state creep rate of $\sim 10^{-7}$ h^{-1} and approximately obeys a pseudo-creep law of the form, $\dot{\varepsilon} \simeq (\sigma/Y)\dot{\varepsilon}_g$, where Y is the yield strength of the material and $\dot{\varepsilon}_g$ the irradiation growth rate of individual crystals. This equation corresponds to a strain-rate exponent of unity and has been demonstrated experimentally by Roberts and Cottrell[5], who used small springs of uranium wire to facilitate measurement of the slow creep-rate. A demonstration of large elongations with tensile forces in these circumstances would not be practical despite the closeness of n to unity. (Calculations based on their results give $n \sim 0{\cdot}8$ using low-deflexion formulae to deduce the appropriate stresses and strain-rates.)

It is demonstrated here that viscous flow can be induced in lightly stressed materials with anisotropic coefficients of thermal expansion, by subjecting them to temperature changes sufficient to create 'spontaneous plasticity'[6]. It is expected, therefore, that under tensile forces and

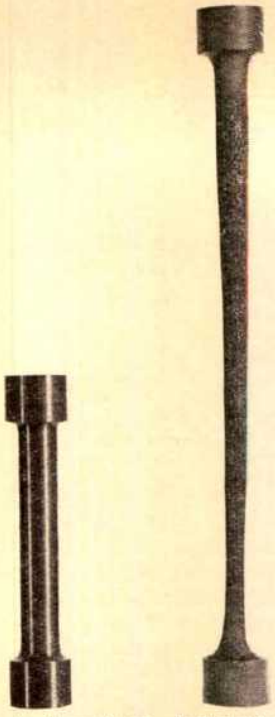

Fig. 1. Uranium tensile specimens. Left, before testing; right, after ~500 cycles between 400° C and 600° C at 11,500 g mm^{-2}

under these conditions any cross-section of a specimen will reduce in area at the same rate, independently of its initial magnitude, to produce extension without enhancing necking.

Superplastic flow in α-uranium is strikingly illustrated in Fig. 1 where the specimen has undergone ~170 per cent elongation. To achieve this the uranium specimen was held under constant stress (~1,150 g mm^{-2}) and the temperature changed from 400° C to 600° C and back to 400° C every 20 min for 7 days. The stress-level was chosen from work[7] in which a linear proportionality between strain-rate and applied stress was established for applied stresses < 2,600 g mm^{-2} and well below those generated internally.

An additional feature of this remarkable ductility in uranium is that mechanisms limiting ductility in normal tensile or creep testing are not relevant to the present case. For example, the continuous reversal of temperature creates conditions where some grain-boundary sliding is likely which reverses in direction at each half-cycle. No evidence of pronounced porosity was metallographically revealed.

Note added in proof. Extensions of 300 per cent without failure or signs of necking have since been achieved. This elongation should be compared with the failure at 55 per cent elongation of a similar specimen when tested under isothermal conditions at 600° C with the same stress.

Crack Initiation during the Fatigue of β-Brass

Metallographic observations on the fatigue damage of β-brass in reversed bending have been reported[1]. A characteristic type of damage was observed in which short markings appeared, normal to, and sometimes on both sides of, some grain boundaries. These markings did not have the same traces as slip within the grain and formed adjacent to, but not in, the grain boundaries.

Further work has been performed on 48·25 at. per cent zinc β-brass fatigued in reversed bending both at room and liquid nitrogen temperatures. A sheet was hot-rolled to about 1·2 mm and specimens cut out in a jig. These were then recrystallized by a short anneal at 830° C and quenched into iced 10 per cent caustic soda. Surface layers were ground off, and specimens electropolished for 6 h in orthophosphoric acid. This ensured an unworked surface, as shown by the etch-pit distribution. A soft-iron pole-piece was attached to the free end of the specimen, which vibrated at resonant frequency under the influence of an alternating magnetic field. The specimen geometry resulted in a frequency from 100 to 300 c/s. The applied stress could not be measured using this arrangement, but after an initial period of work-hardening, a constant frequency was maintained, until fatigue-cracking started.

Cross-slip was frequently observed at room temperature, together with some curved and intersecting slip traces. At −196° C cross-slip was much less frequent, and slip traces tended to be straight.

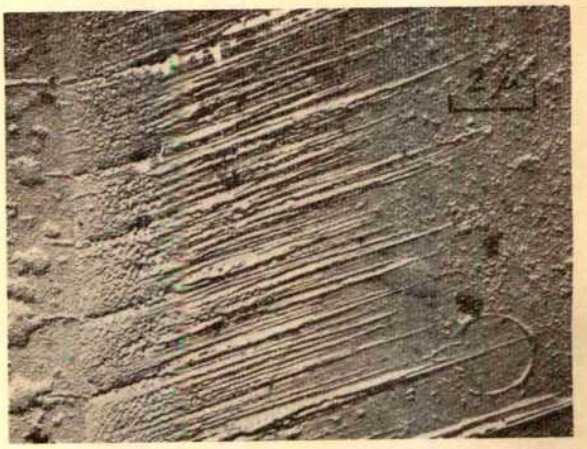

Fig. 1. Electron micrograph of region of short slip markings and cracks next to a grain boundary in β-brass (46·95 at. per cent zinc) fatigued at room temperature. C/Pt replica

At room temperature the more frequent mode of crack initiation was intergranular, either from triple points or along grain boundaries ending at the edge of the specimen. Short markings next to grain boundaries were seen as a second mode of crack initiation. These consisted of very fine markings of the type shown in Fig. 1, extending about 10μ from the grain boundary, but not necessarily on the active slip plane remote from the boundary, interspersed with 'persistent' markings or cracks often at regular intervals. Two surface analyses of these markings showed that they were incipient cracks lying on or close to {110} planes. Both slip and short markings were observed either on one side only or on both sides of the boundary. Cracks longer than others on one side of the boundary were always associated with longer cracks in the second grain. The occurrence of matching cracks across a boundary seemed to be determined by the correspondence of {110} planes in the two crystals. If {110} planes correspond, cracks may easily propagate across the boundary; if not, propagation will be difficult despite stress concentration at the crack

tip. These cracks appeared to form in succession, probably by a process producing slip intensification and a crack by the classical mode of fatigue-crack formation, in which cross-slip is known to be important[2].

The regularity of spacing of short cracks next to the boundary in β-brass seems to indicate that they are formed by the progressive relief of stresses in the grain boundary region. Occasionally one of these cracks propagated, in which case its direction changed a short distance from the boundary in the manner observed by Forsyth[3], such that the direction was influenced by the normal applied stress. Even if a crack had been initiated in the grain boundary, it was frequently found to propagate in a transcrystalline manner.

Specimens were fatigued at −196° C by standing the specimen clamping block in liquid nitrogen inside a Dewar flask. Failure always occurred by the propagation of a cleavage-type crack on {110} planes through the specimen. Again these planes did not always correspond with the active slip planes, which are variously reported as exclusively {110} (ref. 4), and almost exclusively {211} (ref. 5) at −196° C. Intergranular crack initiation was absent. A series of parallel cracks was observed from some grain boundaries (Fig. 2). These cracks had a spacing of about 10μ or more and the longer ones propagated a considerable distance into the grain. Shorter markings were also observed and, on sectioning on a second surface, no cracks were observed, but regions of transformation product were seen to correspond with the markings on the specimen surface (Fig. 3). It has been shown[6] that martensite may be induced in stable β-brass by deformation, so that the occurrence of transformation product indicates an increase in the stress in this region. No martensite was found associated with cleavage-type cracks.

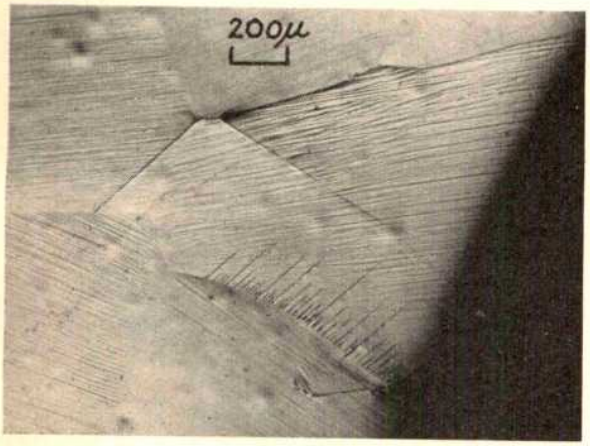

Fig. 2. β-brass (48·25 at. per cent zinc) fatigued $7{\cdot}5 \times 10^6$ cycles at −196° C showing cleavage-type cracks on {110} planes

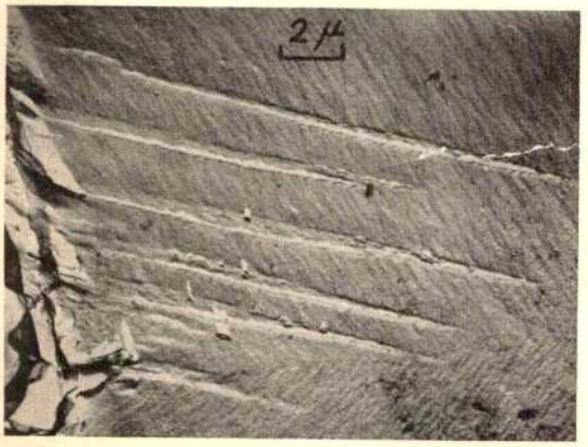

Fig. 3. Same specimen as in Fig. 2. Section through a boundary showing short markings. Transformation product, presumably martensite. Electron micrograph, C/Pt replica

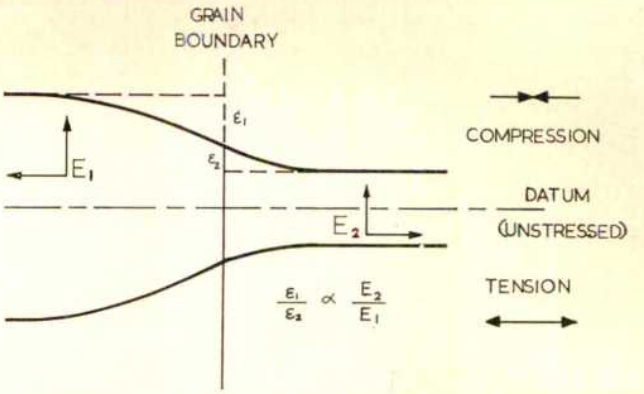

Fig. 4. Simple model to show the origin of elastic stress concentration at a grain boundary in an elastically anisotropic solid

It is proposed that stress concentrations of a sufficient magnitude to produce slip and cracks can arise at a grain boundary if the crystals composing it have a 'soft' and a 'hard' orientation to the applied stress. McManus[7] has investigated the change in the elastic moduli of β-brass with temperature and composition. For a 48·25 at. per cent zinc alloy his results give values of $0{\cdot}249 \times 10^{12}$ and $1{\cdot}94 \times 10^{12}$ dynes/cm² for Young's modulus measured in the <100> and <111> directions, respectively. The low value of $E_{[100]}$ implies weakness to (110) [$\bar{1}$10] shear, as pointed out by Zener[8]. The details of the stress distribution in the neighbourhood of the boundary between two anisotropic crystals will be complex, but a simple model may be postulated which can approximate to these conditions.

Fig. 4 shows the edge of a bicrystal composed of one 'soft' and one 'hard' crystal. On compression the two crystals deform elastically to differing extents, but to maintain coherency across the boundary the soft crystal will deform less in this region and the hard crystal more than in regions remote from the boundary. The magnitude of the lateral deformation in the grain boundary region will be inversely proportional to the ratio of the moduli in that direction. In tension the sign of the stresses will be reversed, but their magnitude will be the same as in compression. Such a stress concentration may be relieved in two ways. Either a crack can be initiated in the grain boundary between the two crystals, or a series of parallel cracks can form normal to the boundary. A grain boundary crack will be a more efficient means of stress relief, and its initiation will be particularly favoured if the boundary terminates in the edge of the specimen. Once the crack has formed, propagation criteria become important and the crack may spread on a transcrystalline path. Short cracks normal to the boundary can be formed when the boundary is limited by triple points. Once such a crack has formed, the stress distribution near it will be changed, and the stress concentration moved along the boundary, allowing more slip to occur and new cracks to form. Short slip markings are sometimes found associated with cracks along the grain boundary. It is possible that an intergranular crack may produce a stress concentration favouring the formation of short slip markings, or that fracture may be completed in a region of short cracks next to the grain boundary by the propagation of an intergranular crack. Short slip markings will be most pronounced a short distance from the boundary because coherency constraints between the two grains will limit the formation of large slip steps at the grain boundary itself. The occurrence of cleavage-type cracks at low temperatures in β-brass is consistent with the increase in brittleness of body-centred cubic metals with falling temperature.

In order to test the importance of elastic stress concentrations at grain boundaries in β-brass during fatigue, the orientation of a number of crystal pairs the mutual boundary of which shows fatigue damage is being determined and examined, with the view of differentiating between the conditions necessary to initiate a crack in an intergranular manner, or to initiate short cracks next to grain boundaries.

CHEMISTRY

Matrix Isolation of Unstable Halogen Radical Ions

We have recently obtained spectroscopic evidence for the formation of reduced metal valency states in γ-irradiated 5·4 M H_2SO_4 glasses at 77° K (reaction (1)

$$M^{n+} + e^-_m \rightarrow M^{(n-1)+} \qquad (1)$$

where M^{n+} = Mn^{2+}, Co^{2+}, Ni^{2+}, Ga^{3-}, Ag^+, Cd^{2+}, In^{3+} and Tl^+)[1]. In the course of this work we have also investigated non-reducible solutes such as sodium chloride and sodium bromide.

Chloride. At relatively high concentrations of sodium chloride (0·1–1·0 M), γ-irradiation at 77° K produced the optical absorption shown in Fig. 1 *A*. The broad band with λ_{max} = 444 mμ and $G\varepsilon^{444m\mu}$ = 3,000 ± 400 is associated with the sulphuric acid, and has been assigned[1,2] to an oxidized radical entity, designated $SO_4^{-}\cdot$, which is formed by either direct action of the γ-rays or electron transfer to OH radicals or, possibly, H_2O^+ ions. The peak with λ_{max} = 335 mμ was observed only when chloride was present in the glass and increased with [NaCl]. In addition sodium chloride reduced the yield of $SO_4^{-}\cdot$. On warming, the 335 mμ absorption increased (Fig. 1 *B*) in the region 135°–150° K, and this is attributed to an increased yield of the entity, rather than a change of extinction coefficient with temperature, since the enhanced absorption persisted on re-cooling the glass to 77° K. Fig. 1 also shows that this change on warming was accompanied by a decrease in the $SO_4^{-}\cdot$ absorption. At 150°–154° K, the 335 mμ band decayed and a new absorption with λ_{max} = 230 mμ (Fig. 1 *C*) was formed, which was still present, although with smaller optical density, at room temperature (Fig. 1 *D*). Re-cooling the system to 154° K gave the larger absorption again (Fig. 1 *C*).

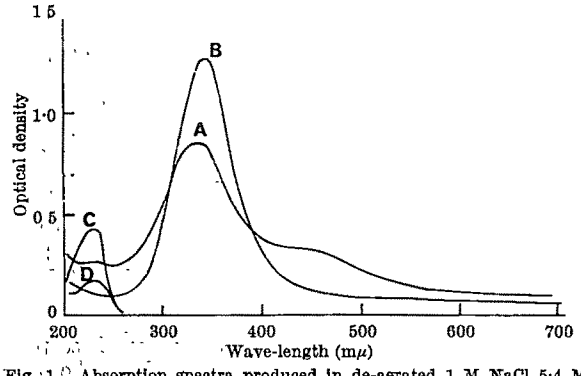

Fig. 1. Absorption spectra produced in de-aerated 1 M NaCl 5·4 M H_2SO_4 by γ-irradiation (1·14 × 10^{19} eV ml.$^{-1}$) at 77° K. *A*, *B*, *C* and *D* are the absorptions at 77°, 135°, 154° and 293° K respectively

The absorption with λ_{max} = 335 mμ is very similar to that reported by Anbar and Thomas[3], in the pulse radiolysis of dilute sodium chloride solutions at *p*H 3, and attributed to Cl_2^-. The assignment of the absorption in the glass phase to this entity seems reasonable, and is consistent with the reduction in the yield of $SO_4^{-}\cdot$, which suggests the formation of a new oxidized species. An electron transfer from a chloride ion to a $SO_4^{-}\cdot$ radical is thought to account for the additional Cl_2^- formed on warming. For [NaCl] = 0·5 M, $G\varepsilon^{335m\mu}_{Cl_2^-}$ (glass phase, 77° K) = 2,600 ± 300 and in view of the room temperature value for $\varepsilon^{\lambda max}_{Cl_2^-}$ of 12,500 ± 1,000[3], this corresponds to a value for $G_{Cl_2^-}$ of ~ 0·2. The high solute concentrations required to give Cl_2^- suggest that it is only formed in cases where two chloride ions are adjacent in the glass and no migration is necessary. Hornig and Osberg[4] have shown by infra-red studies that crystalline HCl exists as antiparallel zigzag chains of hydrogen-bonded molecules, at temperatures below 98° K. If the chloride in H_2SO_4, which exists partly as HCl at room temperature, forms similar chains on freezing to 77° K, a situation will occur in which the chlorine atoms are suitably positioned for the formation of Cl_2^-. The way in which Cl_2^- decays at 150°–154° K is uncertain, but if Cl_2 is a product, equilibrium (2) will exist, and the absorption represented in Fig. 1 *C* may be due to a mixture of

$$Cl_2 + Cl^- \rightleftarrows Cl_3^- \qquad (2)$$

Cl_2 and Cl_3^-[5]. Furthermore, the reversible change in the magnitude of the absorption on warming may be a result of the temperature dependence of the equilibrium constant.

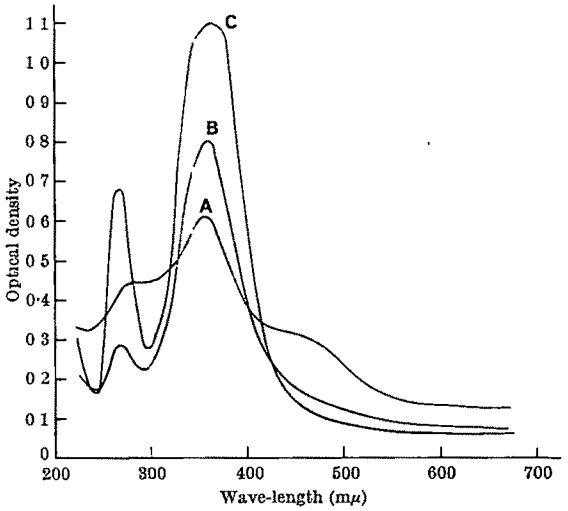

Fig. 2. Absorption spectra produced in de-aerated 0·4 M NaBr 5·4 M H_2SO_4 by γ-irradiation (1·14 × 10^{19} eV ml.$^{-1}$) at 77° K. *A*, *B*, and *C* are the absorptions at 77°, 132° and 143° K respectively

Bromide. The behaviour of γ-irradiated NaBr – H_2SO_4 glasses was found to be similar to that described for NaCl – H_2SO_4 glasses. The absorption produced by irradiation at 77° K is shown in Fig. 2 *A*; and the new absorption with λ_{max} = 355 mμ can be correlated with the liquid phase spectrum of Br_2^- obtained by the pulse radiolysis of bromide solutions[6]. Warming to 130°–145° K enhanced the 355 mμ peak and the absorption present as a shoulder (λ_{max} 270 mμ) at 77° K was also observed to increase (Fig. 2 *B* and *C*). This latter absorption is attributed to Br_3^-, on the basis of its similarity to that reported in the liquid phase[6]. At 150°–155° K the 355 mμ absorption decayed while that due to Br_3^- increased further and remained on warming to room temperature.

Iodine. Sodium iodide is oxidized by concentrated sulphuric acid at room temperature and the strong optical absorption of the product I_3^-, made spectroscopic work impossible at high solute concentrations. However, glasses made from 5·4 M sulphuric acid saturated with iodine ($[I_2] \sim 10^{-3}$ M) gave on γ-irradiation at 77° K a weak new absorption in the region of 380 mμ, which is where an absorption due to I_2^- has been observed in liquid water[7]. The formation of mobile electrons in γ-irradiated acid glasses has already been established[1,8] and in this case it appears that a simple reduction is occurring (reaction (3)).

$$I_2 + e^-_m \rightarrow I_2^- \qquad (3)$$

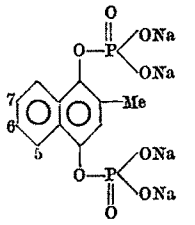
Stability of a Radioactive Drug—Tetrasodium 2-Methyl-1,4-naphthaquinol Diphosphate labelled with Tritium

This communication describes the decomposition by self-irradiation of the radioactive drug tetrasodium 2-methyl-1,4-naphthaquinol diphosphate labelled in the 5,6 and/or 7 positions with tritium. The possible radiotherapeutic use of this labelled compound in the treatment of certain types of cancer is at present under investigation by Prof. J. S. Mitchell and colleagues at the University of Cambridge[1,2].



The peculiar property of radioactive organic compounds to undergo decomposition by self-irradiation on storage presents a difficult, but not an insoluble, problem in the use of such compounds. This property is particularly evident with tritium compounds, where almost all the β-radiation energy is self-absorbed by the compound.

Some of the governing principles and modes by which decomposition by self-irradiation can occur have already been published[3–5]. Decomposition by natural decay of the tritium atoms to helium-3 cannot be controlled, but fortunately this effect contributes little (less than 6 per cent per annum) to the total decomposition in relatively small molecules such as the naphthaquinol diphosphate. It is the secondary effects which are the more important and difficult to control; that is, the interaction of the labelled molecules with activated species such as free radicals or the excited products of primary decay. For radiotherapeutic use tritiated tetrasodium 2-methyl-1,4-naphthaquinol diphosphate is required at the highest possible specific activity, a requirement at which such secondary decomposition effects are most pronounced.

No method has yet been found to eliminate completely the decomposition, but certain measures can be taken to minimize its effect[6]. These are: (*a*) reduction of the effective radiation dose to the compound; for tetrasodium 2-methyl-1,4-naphthaquinol-T diphosphate this is done by storing the compound in aqueous solution; (*b*) lowering the temperature, thereby minimizing secondary (temperature dependent) effects by reducing the thermal activation energy of the excited species; (*c*) the addition of free radical scavengers; this method was not investigated for the tritiated drug which was required at high chemical purity.

A few results concerning the stability of tetrasodium 2-methyl-1,4-naphthaquinol diphosphate, labelled in the 6-position with tritium and stored in aqueous solution at 0° C, were published in 1962 (ref. 7). The results of a more extensive investigation are summarized in Table 1.

Table 1. Decomposition of Tritiated Tetrasodium 2-Methyl-1,4-naphthaquinol Diphosphate in Isotonic Saline Solution

Position of tritium atoms	Specific activity (c./mmole)	Radioactive concentration (mc /ml.)	Storage temp. (°C)	Storage time (months)	Energy absorbed (rads)	G(-M)	Decomposition (per cent)
6	27	390	2	10	$3\,5 \times 10^7$	0·3	75
6	29	390	2	3	$1·1 \times 10^7$	0·3	25
6	29	390	−80	3	$1·1 \times 10^7$	0·5	40
6	27	2	−196	6	$1·1 \times 10^6$	0·06	10
6	27	240	−196	6	$1·3 \times 10^7$	0·06	10
6	27	2	−196	6	$1·1 \times 10^5$	0·03	5
6	27	266	−196	6	$1·4 \times 10^7$	0 08	12
6, 7	10	1	20	0·33	3×10^3	8	23
6, 7	10	1	20	0·17	$1·5 \times 10^3$	7	10
6, 7	54	300	−40	1	$2·7 \times 10^6$	1	50
6, 7	20	247	−196	3·5	$7·8 \times 10^6$	0 14	9
6, 7	55	360	−196	3	$9\,7 \times 10^6$	0 06	9
6, 7	59	655	−196	2·75	$1·6 \times 10^7$	0·07	10
5, 6, 7	87	560	2	6	$3·0 \times 10^7$	0·2	95
5, 6, 7	76	360	2	3	$9\,7 \times 10^6$	0·1	20
5, 6, 7	76	360	−80	3	$9·7 \times 10^6$	0·14	30
5, 6, 7	65	344	−80	0·5	$1·6 \times 10^6$	1·5	45

The tritiated drug was stored under nitrogen in sterilized isotonic saline solution, and the radiochemical purity determined after various time intervals, by paper chromatography (Whatman No. 1) using *n*-butanol : water : acetic acid (12 : 5 : 3) and *n*-propanol : ethanol : water : conc. ammonia (30 : 30 : 39 : 1) as the eluting solvents.

The rate of decomposition in solution at room temperature (20° C) at concentrations above 100 mc./ml. is approximately 10 per cent in 24 h, at these high specific activities. The rate is reduced to 1–2 per cent per day if the radioactive concentration is lowered to 1 mc./ml. It is therefore essential to keep solutions of the drug cool. However, an interesting observation is that the decomposition rate in frozen solutions (at temperatures down to − 80° C) is greater than in solution at + 2° C, a phenomenon also observed with solutions of tritiated thymidine[6,9]. The reason for this increased (and erratic) decomposition in the frozen state may be due to 'clusters' of radioactive molecules in the ice giving rise to local pockets of highly concentrated radiation. On several occasions when examining frozen solutions of the tritiated quinol, brown areas were observed in the ice as if decomposition was occurring at definite centres. A similar explanation for the increased decomposition rate of tritiated thymidine in frozen solutions has been proposed by Apelgot *et al.*[10–12].

Storage of the tritiated drug in solution at liquid nitrogen temperature (−196° C) reduces the rate of decomposition by a factor of at least five and at this low temperature the decomposition rate is almost independent of the radioactive concentration in the range studied.

Less than 10 per cent tritium is actually lost from the molecule by exchange into the aqueous solution during 1 year storage, but the decomposition of the tritiated tetrasodium 2-methyl-1,4-naphthaquinol diphosphate gives rise to three major decomposition products which have not yet been identified.

In the use of this tritiated drug, necessarily required at very high specific activity for radiotherapy, these problems of decomposition by self-irradiation should be borne very much in mind by the cautious experimenter.

I thank Dr. W. P. Grove and Dr. J. R. Catch for their interest in this work.

Chromatographic Separation of Argon and Oxygen using Molecular Sieve

THE chromatographic separation of argon and oxygen is difficult, and existing methods depend on one of the following techniques:

(1) Separation on a molecular sieve 5 Å column at 18° C (ref. 1) and at −80° C (refs. 2–4).

(2) Chromatographing argon and oxygen as a composite peak on molecular sieve 5 Å at 100° C; removal of the oxygen with a reducing agent allows the argon peak only to be developed[5–7].

(3) Separation of argon and oxygen on a column of firebrick loaded with 8 per cent by weight of blood at 20° C (refs. 8 and 9).

It was noticed[10] that after a molecular sieve column was heated above the normal reactivation temperature of 300° C a partial separation of argon and oxygen resulted at a column temperature of 25° C. The operating parameters for optimum separation of argon and oxygen and the constancy of resolution with time have been investigated at this Laboratory using a molecular sieve 5 Å column. A helium ionization chromatograph[11] was used for this work.

The chromatographic column (5 ft. × 3/16 in. internal diameter stainless steel tube) was packed with Linde molecular sieve 5 Å (calcium alumino-silicate, 30–60 mesh) which had been previously heated to 400° C in air. The column was coupled to a helium ionization chromatograph and the molecular sieve heated to a minimum of 400° C for 24 h with a pure helium purge. Higher activating temperatures (for example, 500° C) do not appear to increase the efficiency of separation and the use of normal cylinder helium (no purification) does not give the required degree of reactivation.

A column treated in the foregoing manner gave the following relative retention times:

Hydrogen	Argon	Oxygen	Nitrogen	Methane
1·00	1·57	1·89	2·89	4·07

for a column temperature of 75° C and a helium flow rate of 67 ml./min. It was found that slight deterioration in resolution occurred over a 5-day period. This deterioration produced an increase in the argon retention time and a decrease in the oxygen retention time. Reactivation of the column at 400° C for 16 h gave the original retention times.

The effect of 'swamping' a small peak by a large amount of one component was found to be negligible for the range of volumes tested. A return to baseline between the argon and oxygen peaks was found for amounts of 20 μml. argon and 200 μml. oxygen and for 200 μml. argon and 19 μml. oxygen.

The sensitivity for both argon and oxygen was of the order of 1 μml. where the sensitivity is defined as five times the noise-level. A detector voltage of 500 V was used.

Microwave Stimulation of Chemical Reactions

DURING an investigation of the effects of microwave energy on organic reactions, a novel application of such radiation has been disclosed. One well-known difficulty in the examination of solid-state pyrolytic reactions is that, perforce, for each particle, the products move from the site of their production against a positive temperature gradient. For any sizable particle, therefore, the pyrolysate is subject to further decomposition and, in many cases, it is impossible to isolate the primary products.

It has now been found that certain organic solids, notably coal and some similar substances, are effectively decomposed by microwaves and that the nature of the cracked product is different from that produced by purely thermal means. The reason for this difference is, I believe, because the microwaves decompose the material from the 'inside' outwards.

Small pieces of gas coal, about 1 c.c., are more or less instantaneously decomposed into a heavy tar precursor and a soft carbonaceous residue.

A Philips 7292 magnetron has been used and our equipment is a development of that of McTaggart[1]. The solids (1–3 g) are placed across the field in a wave-guide, within silica tubes, through which flows a slow current of nitrogen; the pressure is atmospheric. In the case of a typical gas coal, on switching on the anode current, within 2 sec heavy brown vapours were evolved which 'flowed' down the exit tube. The fog could not be effectively condensed by a liquid air trap but was collected by a packed plug of cotton wool. When allowed to deposit on surfaces, the fog coalesced to an orange varnish-like film, whereas, 'upstream' from the sample, the interior of the containing tube was covered for a short distance with a fine brown powder which, under the microscope, appeared as resinous particles. Immediately adjacent to the sample, the wall of the tube was covered with a carbon mirror, the inner surface of which was coated with fine carbon black. The residual coke was soft and friable. We have been unsuccessful, so far, in isolating the more conventional liquid products, such as are contained in 'light oil', etc.

The duration of the complete decomposition is so short (about 15 sec) that a conventional thermocouple placed outside the walls of the reaction tube does not have time to respond, although, if the power (700 W) be left on for 20–30 sec, the coke is raised to incandescence. Presumably, at lower power, uniform slow heating can be achieved.

With all coals, the decomposition was immediate and complete. With oil shales, there was often an induction period before reaction, whereas essentially aliphatic substances, such as torbanites, appeared transparent.

At this stage, only preliminary work has been done, but it is obvious that some organic substances are highly absorbent of microwave energy. As the energy can be directed and made to penetrate, it is thought that microwaves may provide a new tool with which to explore certain pyrolysis reactions without some of the inherent disadvantages of more conventional means.

Free Energy Functions and Deviations in Thermochemical Data Storage for Inorganic Compounds

THE compilation of the results of measurements of thermochemical properties is a task which is growing rapidly in magnitude as our experimental skills are advanced. Whereas a few years ago the reliable data were few, the rate of publication has now achieved a scale requiring the preparation of specialized abstracts.

In considering means for preserving the results, the twin aspects of ease of access and accuracy of presentation often work against one another, and the earlier methods of using polynomial equations with temperature as a variable are becoming superseded by tables of the so-called free-energy function. The proponents of this latter method[1] argue that the function:

$$\text{free-energy function} = -\left[\frac{G^\circ_T - H^\circ_{298}}{T}\right]$$

varies smoothly with temperature and thus interpolation is simple when only a small number of values of the free energy function at a few chosen temperatures, that is, at 500° intervals, are given.

This is true, but the free-energy function does introduce a severe measure of inflexibility into the system of data storage. This is because the entropy at 298° K and the heat capacities which were available at the time of the compilation are indissolubly locked into the values of the free-energy function which are tabulated. A change in any one of these renders the values inaccurate and therefore the tabulations useless.

The polynomial method of presentation has the merit of clearly demonstrating which data were used, while the free-energy function does not. On the other hand, it leads to very tedious calculations the value of which is sometimes doubted before one begins, because the experimental data are not very accurate.

Ellingham[2] proposed a very elegant solution to the problem when he showed that a simple two-term equation gave a close approximation to the actual values of free energy changes for a number of simple reactions. This procedure has the merit of being not very time-consuming in application, and being a sufficient approximation in most instances in the light of the data which are available.

It is proposed here to elaborate a simple method of using data in which a high precision can be obtained for the values of free-energy changes when the data will allow, in which the relative importance of the degrees of elaboration can be compared, and in which new and more accurate data can be immediately incorporated.

It is obviously useful to separate the contributions of low-temperature calorimetry (up to 298° K) to our knowledge from the high-temperature data. These measurements are usually made quite independently of high-temperature measurements both in location and in time, and hence they are likely to change at a different time. We thus choose as our starting point a simple two-term free-energy equation based on ΔS°_{298} and ΔH°_{298}:

$$\Delta G^\circ_T = \Delta H^\circ_{298} - T\Delta S^\circ_{298} \qquad (1)$$

Provided there are no heat-capacity contributions above room temperature, this equation provides a simple means of calculating high-temperature free-energies. However, there always will be such contributions and we shall define the 'free-energy deviation' which is the difference between the correct value and that predicted by equation (1) in terms of heat-capacity equations. Kelley[3] has recommended from a survey of the available data the use of a heat-capacity equation of the general form:

$$Cp = \alpha + \beta T + \gamma T^{-2} \qquad (2)$$

We shall use this form in evaluating the 'free-energy deviation function':

$$\text{free-energy deviation} = \frac{1}{T}(H_T - H_{298}) - (S_T - S_{298})$$

$$= \frac{1}{T}\int_{298}^{T} Cp.\mathrm{d}T - \int_{298}^{T}\frac{Cp}{T}.\,\mathrm{d}T$$

Obviously for a chemical reaction:

Δ free-energy deviation = free-energy deviation (products) − free-energy deviation (reactants).

Calling now the ratio $298/T$ by the symbol θ and using Kelley's equation for the heat capacity:

$$\text{free-energy deviation} = \alpha(1 - \theta + \ln\theta) + \beta T\left(\theta - \tfrac{1}{2} - \frac{\theta^2}{2}\right) + \frac{\gamma}{T^2}\left(\frac{1}{\theta} - \frac{1}{2\theta^2} - \tfrac{1}{2}\right) \qquad (3)$$

or for the polynomial:

$$Cp = \alpha + \beta T + \gamma T^2 + \delta T^3 \ldots \nu T^{n-1}$$

the general term in free-energy deviation is:

$$\nu T^{n-1}\left\{\frac{\theta^{n-1}}{n-1} - \frac{\theta^n}{n} - \frac{1}{n(n-1)}\right\} \qquad (4)$$

If the free-energy deviation function is multiplied by the temperature, then the value of the free energy which must be added to equation (1) to get the accurate value is obtained. The functions in θ are universal functions to all systems whereas the individual values of α, β, γ, etc., belong to each substance characteristically. Table 1 shows the values of the θ functions multiplied by temperature at 200° K intervals and these should be used in a graphical form to aid interpolation.

An example of the use of these figures is as follows:

For the free energy of formation of La_2O_3 (*c*) from lanthanum solid and oxygen, Coughlin[4] presents the following data:

For $2La(c) + \frac{3}{2}O_2 \rightarrow La_2O_3(c)$

$\Delta H^\circ_{298} = -428,570$ cal ; $\Delta S^\circ_{298} = -72{\cdot}62$ cal/deg.

Heat capacities:

$La_2O_3\,(c)$; $Cp = 28{\cdot}86 + 3{\cdot}10 \times 10^{-3}T - 3{\cdot}28 \times 10^5 T^{-2}$ cal

$2La\,(c)$; $Cp = 12{\cdot}34 + 3{\cdot}2 \times 10^{-3}T$ cal

$\frac{3}{2}O_2\,(g)$; $Cp = 10{\cdot}74 + 1{\cdot}50 \times 10^{-3}T - 0{\cdot}60 \times 10^5 T^{-2}$ cal

and derives the equation:

$$\Delta G^\circ_T = -431,120 - 13{\cdot}31\,T\log T + 0{\cdot}80 \times 10^{-3}T^2 + 1{\cdot}34 \times 10^5 T^{-1} + 112{\cdot}36T \text{ cal.} \qquad (5)$$

This yields at the melting-point of lanthanum (1,153° K):

$\Delta G^\circ_{1153} = -347,290$ cal $\Delta H^\circ_{1153} = -425,290$ cal

$\Delta S^\circ_{1153} = -67{\cdot}57$ cal/deg.

Using equation (1) we would find:

$$\Delta G^\circ_{1153} = -344,770 \text{ cal}$$

A difference of 2,520 cal has appeared between the value calculated from the simple equation using 298° K. data only and the more complicated equation (5). For many purposes this is a small difference which can be neglected, especially since the uncertainties in the original data are often as big as this.

Table 1 FREE-ENERGY CONTRIBUTIONS USING KELLEY'S HEAT CAPACITY FUNCTION: $Cp = \alpha + \beta T + \gamma T^{-2}$ cal

$T°$ K	$T(1-\theta+\ln\theta)$cal	$T^2\left(\theta-\frac{\theta^2}{2}-\frac{1}{2}\right)$	$\frac{1}{T}\left(\frac{1}{\theta}-\frac{1}{2\theta^2}-\frac{1}{2}\right)$
400	−2	$-0{\cdot}48\times10^4$	$-1{\cdot}74\times10^{-4}$
600	$-11{\cdot}8\times10$	$-4{\cdot}60\times10^4$	$-8{\cdot}16\times10^{-4}$
800	$-29{\cdot}8\times10$	$-12{\cdot}63\times10^4$	$17{\cdot}5\times10^{-4}$
1,000	$-51{\cdot}8\times10$	$-24{\cdot}50\times10^4$	$-26{\cdot}9\times10^{-4}$
1,200	$-76{\cdot}6\times10$	$-40{\cdot}30\times10^4$	$-40{\cdot}3\times10^{-4}$
1,400	$-106{\cdot}9\times10$	$-60{\cdot}50\times10^4$	$-49{\cdot}5\times10^{-4}$
1,600	$-138{\cdot}6\times10$	$-85{\cdot}0\times10^4$	$-59{\cdot}0\times10^{-4}$
1,800	$-173{\cdot}6\times10$	$-112{\cdot}9\times10^4$	$-74{\cdot}4\times10^{-4}$
2,000	$-212{\cdot}0\times10$	$-144{\cdot}4\times10^4$	$-93{\cdot}0\times10^{-4}$

The fact that the correction involved by the use of heat-capacity data is so small can readily be seen by working out $\Delta\alpha$, $\Delta\beta$ and $\Delta\gamma$ from the heat-capacity equations, looking for the values of the θ functions at the appropriate temperature and working out the products. These are −4,040 cal for the first term, +593 cal for the second, and +858 cal for the third term. The balance −2,589 cal, obtained by this graphical procedure, is close to that calculated by the use of the polynomial equation (5). The procedure proposed here, however, shows the relative importance of each part of the heat capacity functions in contributing to the correction to the simple equation (1).

The present procedure has not only the advantage of making each contribution to the final value clear, but if at any time new data become available these can readily be used without destroying a lot of effort.

Effect of Temperature on the γ-Radiolysis of Water Vapour

IT has been suggested recently[1] that observed yields[1,2] ($g(-H_2O) \sim 7 \pm 1$) from the radiolysis of water vapour in the presence of chemical scavengers could be explained by considering the energetics of charge neutralization of the hydrated species $H_3O^+(H_2O)_n$ (reaction 1) instead of the simple hydronium ion H_3O^+ (reaction 2):

	$\Delta H°$ (kcal/mole)	
$H_3O^+(H_2O)_n + e^- \rightarrow H + (n+1)H_2O$	> -120	(1)
$H_3O^+ + e^- \rightarrow 2H + OH$	$-(22–26)$	(2)

Support for this hypothesis is provided by the mass spectrometric investigations of Kebarle and Hogg[3] and of Knewstubb and Tickner[4], who have identified hydrates of the form $H_3O^+(H_2O)_n$, with $n = 1 - 7$, using α-radiation and electric discharges in water vapour. This communication presents preliminary evidence, principally from the radiolysis of water vapour containing 5 mole per cent *cyclo*hexane, with some supporting evidence from work with the system water/ammonia, which demonstrates the chemical consequences of reactions (1) and (2), and enables us to estimate the enthalpy change in the general hydration reaction:

$$H_3O^+ + nH_2O \underset{3b}{\overset{3a}{\rightleftarrows}} H_3O^+(H_2O)_n \qquad (3)$$

Values of $G(H_2)$ from the cobalt-60 γ-radiolysis of water vapour ($P \sim 1{\cdot}5$ atm.) were measured at a concentration of 5 mole per cent C_6H_{12}, which is sufficient to scavenge all the H atoms produced[2], and these are corrected for the contribution from energy absorption in C_6H_{12} itself, which was determined by irradiating pure C_6H_{12} over the same range of temperature (Fig. 1). The yield of H_2 from C_6H_{12} is constant ($G(H_2) = 7{\cdot}93 \pm 0{\cdot}19$) at temperatures from 120° C to 340° C and agrees with Freeman's data[5] ($G(H_2) = 8{\cdot}0$) for α-irradiation at 120° C, but it increases rapidly at higher temperatures. This observation, which was incidental to the main object of the work, is similar to the effect of temperature on the radiolysis of benzene[6].

With C_6H_{12} as scavenger the mean yields for H_2 from water vapour are $G(H_2) = 7{\cdot}0 \pm 0{\cdot}4$ over the temperature range 120° –240° C and $G(H_2) = 10{\cdot}6 \pm 0{\cdot}6$ at temperatures >300° C. We attribute the increased yield to a decrease in the stability of the ion-molecule clusters, with a change in the charge neutralization process from reaction (1) to reaction (2). If this is so, then below 240° C $G(H_2) = g(H) + g(H_2) + g(e^-)$, and above 300° C $G(H_2) = g(H) + g(H_2) + 2g(e^-)$ ($g(X)$ represents primary yields and $G(X)$ represents experimental yields). Thus the difference in the observed yields gives $g(e^-) = 3{\cdot}6$, which agrees with the theoretical value of $g(e^-) = 3{\cdot}57$–$3{\cdot}28$ based on $W(H_2O) = 28$–30 eV (refs. 7–9). The interpretation of data from work with H_2O/NH_3 is complicated by the possibility of proton transfer to NH_3, with a consequential change in the nature and energetics of the charge neutralization reactions, but the difference in H_2 and N_2 yields between 240° C and 340° C leads to a value of $g(e^-) \simeq 3{\cdot}5$. Moreover, yields for the disappearance of NH_3 in the system $H_2O/NH_3/O_2$ at 120° C and 300° C are respectively $G(-NH_3) = 6{\cdot}52 \pm 0{\cdot}16$ and $G(-NH_3) = 9{\cdot}83 \pm 0{\cdot}33$ with the difference giving $g(e^-) = 3{\cdot}3$. The results with added NH_3 thus support the conclusions from the work using C_6H_{12}. Increased pressure in the region of 300° C causes a reduction in the enhanced yield, an effect which is predictable from the equilibrium represented by equation (3), giving added confidence to the foregoing interpretation. Quantitative data on the effect of pressure will be published at a later date.

While the shape of the curve for $G(H_2)$ production from H_2O/C_6H_{12} as a function of temperature is not yet closely established, we can estimate the change in enthalpy involved in the general hydration reaction (3). On the basis of the foregoing ideas we write the general equation:

$$G(H_2) = g(H) + g(H_2) + 2xg(e^-) + (1-x)g(e^-) \qquad (4)$$

where x represents the fraction of ions present as H_3O^+ (or a low molecular weight hydrate) which gives reaction (2) on charge neutralization, and $(1-x)$ is the fraction of ions which are neutralized in reaction (1). By taking values for $G(H_2)$ in the temperature-sensitive region from the broken line in the figure, we have calculated relative equilibrium constants as a function of temperature:

$$K_{\text{Dissoc.}} = [H_3O^+]/[H_3O^+(H_2O)_n] \qquad (5)$$

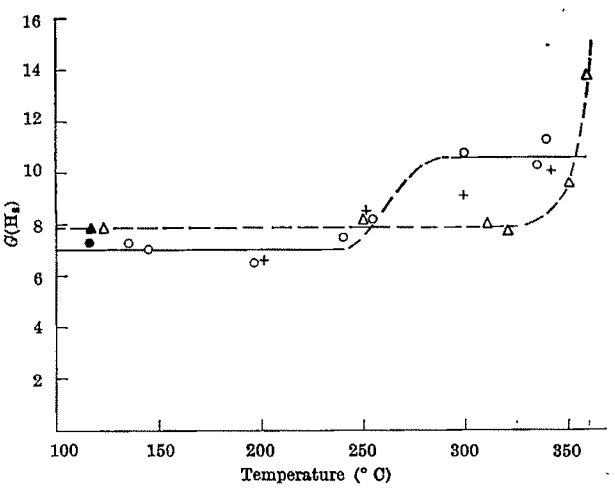

Fig. 1. Cobalt-60 γ-irradiation of water vapour as a function of temperature. Pressure ~1·5 atm; $[C_6H_{12}] \sim 5$ mole per cent. ○, Water vapour corrected for contribution from C_6H_{12}; △, pure C_6H_{12}; ●, ref. 2; ▲, ref. 5; +, H_2O/NH_3, $[NH_3] \sim 0{\cdot}7$ mole per cent

which leads to a value of $\Delta H^0 = 78$ kcal mole^{-1} on solution of the van't Hoff equation. This enthalpy change represents a minimum value for the heat absorbed in the endothermic process 3*b*, and we can write the general equation:

$$H_3O^+(H_2O)_n + 78 \text{ kcal} \rightleftarrows H_3O^+(H_2O)_{n-y} + yH_2O \xrightarrow{e^-} 2H + OH + nH_2O \quad (6)$$

where $y \leqslant n$.

Standard enthalpies of formation (kcal/mole) of the ground state in the gas phase are[10]: $\Delta H^0_f(H_2O) = -58$, (H) = 52, (OH) = 10, and the proton affinity of H_2O is 167–171 kcal/mole[11]. From these data and equation 6 we obtain $\Delta H^0_f(H_3O^+) = 138$ kcal/mole and $\Delta H^0_f(H_3O^+(H_2O)_n) = 38–58n$ kcal/mole. Thus from equation (3) the full hydration energy of H_3O^+ in the vapour phase is calculated to be ~ 100 kcal/mole which agrees with the best estimated value[12] for solvation of H_3O^+ in liquid H_2O, that is, ~ 100 kcal/mole. In view of the uncertainties involved the excellent agreement is probably fortuitous, since (*a*) we are considering only a general equilibrium constant represented by equation (5) instead of the individual stages:

$$H_3O^+(H_2O)_n \rightleftarrows H_3O^+(H_2O)_{n-1} + H_2O \rightleftarrows H_3O^+(H_2O)_{n-2} + 2H_2O \quad (7)$$
